Should a Bot be Sarcastic?
Understanding User Preferences Towards Sarcasm Generation

Anonymous ACL submission

Abstract

Previous sarcasm generation research has focused on how to generate text that people perceive as sarcastic to create more human-like interactions. In this paper, we argue that we should first turn our attention to the question of when sarcasm should be generated, finding that humans consider sarcastic responses inappropriate to many input utterances. Next, we use a theory-driven framework for generating sarcastic responses, which allows us to control the linguistic devices included during generation. For each device, we investigate how much humans associate it with sarcasm, finding that pragmatic insincerity and emotional markers are devices crucial for making sarcasm recognisable.

1 Introduction

The prevalence of sarcasm on the social web (Khedak et al., 2018; Sykora et al., 2020) has motivated computational investigations across the NLP community. Most focus on textual sarcasm detection, the task of classifying whether or not a given text is sarcastic (Riloff et al., 2013; Joshi et al., 2016; Wallace et al., 2015; Rajadesingan et al., 2015; Bamman and Smith, 2015; Amir et al., 2016; Hazarika et al., 2018; Oprea and Magdy, 2019).

A recent research direction considers sarcasm generation. Approaches to sarcasm generation introduced so far (Joshi et al., 2015; Mishra et al., 2019; Chakrabarty et al., 2020) are mainly motivated by the potential to create more approachable, human-like conversational agents, considering that sarcasm is a natural part of human discourse. We suggest reconsidering this motivation, as a community, for two reasons.

First, in human discourse, sarcasm is not a communicative goal in itself. Rather, it can be used to achieve a wide variety of goals. Some of these goals, such as to diminish the impact of criticism (Dews and Winner, 1995), to create humour (Kreuz et al., 1991; Colston and O’Brien, 2000b,a), to praise (Bruntsch and Ruch, 2017), or to strengthen relationships (Jorgensen, 1996; Pexman and Zvaigzne, 2004), might be desirable in human-machine interactions as well. However, other goals, such as criticising, mocking, or expressing dissociation, often with surface contempt or derogation (Wilson, 2006), might not be desirable in human-machine interactions.

Second, the communicative goals mentioned above were observed in human interactions. Even when a machine seeks potentially desirable goals, it is unclear whether sarcastic utterances have the same effect on humans when coming from machines.

Therefore, we suggest it is imperative, not least from an ethical perspective, to consider the following research questions:

1. RQ1. When should a bot be sarcastic?
   (a) When do humans consider sarcasm appropriate?
   (b) When do humans prefer sarcasm, over non-sarcasm?

2. RQ2. How should a bot formulate sarcasm?
   (a) What linguistic devices do humans associate with sarcasm?
   (b) What sarcasm flavour do they prefer?

Here, by flavour, we mean a specific conjunction of linguistic devices that humans may associate with sarcasm, such as intensifiers and emotional markers, as introduced in Section 3, and expanded upon in Section 4.

To address our research questions, we suggest the following approach. First, given a set of input utterances, generate several sarcastic responses. Each response should be of a specific sarcasm flavour, i.e. should display a specific conjunction of linguistic devices. Next, create a survey that asks human participants: to indicate how appropriate it was to respond sarcastically to the input; to select their preferred response; and to rate the sarcastic-
ness of each response, investigating whether they associate the linguistic devices in the response with sarcasm.

To achieve this, we require a sarcastic response generator that provides control over the linguistic devices used. Previous generators rely on variants of the traditional theory of sarcasm, which claims that the intended meaning concealed by sarcasm is the opposite of the literal meaning. However, this theory provides a grounding that is neither necessary, nor sufficient, for sarcasm to occur, as discussed in Section 3. To overcome this limitation, we first select a formal theory that, from a linguistic-theoretical perspective, specifies devices whose presence is both necessary and sufficient to unambiguously differentiate sarcasm from non-sarcasm. These are allusion to a failed expectation, pragmatic insincerity, and emotional markers. Grounded on this theory, we propose Chandler,\(^1\) a modular sarcastic response generation framework. The role of Chandler is to generate sarcasm of different flavours and allow control over the flavour used, rather than to necessarily generate the most sarcastic responses possible. We also compare Chandler’s outputs to those of previously proposed generators to examine participant preferences toward an even greater range of sarcasm flavours.

Our results indicate that people find sarcastic responses inappropriate for most input utterances. When sarcasm was considered appropriate, the inputs commonly had a positive sentiment, and often had elements of humour. Further, even when considered appropriate, people still did not usually prefer sarcastic responses over non-sarcastic ones. Sarcasm was typically preferred when it was also considered funny and not too specific. Finally, we identified pragmatic insincerity and emotional markers (cf. Section 3) as crucial linguistic devices to include in generating recognizable sarcasm.

We summarise our contributions as follows. First, our approach allows us to understand people’s preferences about when sarcasm should be used, and how it should be formulated. Using this information, we provide guidelines for future work in sarcasm generation. Second, observing people’s preferences also allows us to quantitatively evaluate the practical advantages of the formal linguistic theory that grounds Chandler.

\(^{1}\)Inspired by the popular TV sitcom.

2 Related Work

The earliest work on sarcasm generation is that of Joshi et al. (2015), who introduce SarcasmBot, a sarcastic response generation system. SarcasmBot uses one of eight possible generators, each containing a set of predefined patterns, one of which is instantiated as the response. The generators do not in fact account for the meaning of the input, rather, they only focus on aspects such as the overall sentiment or presence of swear words. Further, in our experiments, we noticed that most of the time a fallback generator was employed, returning the simple concatenation of a random positive phrase to a random negative one, from a set of predefined phrases that have no specific connection to the input.

Mishra et al. (2019) suggest a sarcastic paraphrase generator. They assume that the input is always of negative polarity, and suggest an unsupervised pipeline of four modules to convert such an input \(u(-)\) to a sarcastic version. In the Sentiment Neutralisation module, they filter out negative sentiment words from \(u(-)\) to produce \(u(0)\). In the Positive Sentiment Induction module, they modify \(u(0)\) to convey positive sentiment, producing \(u(+,−)\). Next, in the Negative Situation Retrieval module, they mine a phrase \(v(-)\) that expresses a negative situation. \(v(-)\) is selected from a set of predefined phrases, based on the similarity to the original input. Finally, the Sarcasm Synthesis module constructs the sarcastic paraphrase from \(u(+)\) and \(v(-)\).

Chakrabarty et al. (2020) suggest a similar pipeline. Their \(R^3\) system first employs a Reversal of Valence module, which replaces input words of negative valence with their lexical antonyms using WordNet (Miller, 1995) to produce \(u(+)\). Next, it builds an utterance \(v\) that is incongruous to \(u(+)\), and generates sarcasm from \(u(+)\) and \(v\).

Previous generators share a limitation that make them unfit for our purposes. Mainly, relying on the traditional theory, they identify sarcasm with linguistic incongruity. Thus, they only provide this single device for investigation, device that is not sufficient for sarcasm to occur, as discussed in Section 3. A further limitation, shared by Mishra et al. (2019) and Chakrabarty et al. (2020), is that their generators only work with input utterances of negative sentiment. However, as discussed earlier, sarcastic communication can have many goals, including to praise, or to strengthen friendships.
3 Linguistic Grounding

Previous Theories In the traditional theories, sarcasm is created by literally saying one thing but figuratively meaning, or conversationally implicating (Grice, 1975), the opposite. However, such incongruity is not necessary for sarcasm. To see this, consider sarcastic understatement such as saying “This was not the best movie ever” to mean the movie was bad. It is also not sufficient. For instance, it also occurs in the construction of certain stylistic devices, such as metaphors, e.g. “Time is money”. Further theories have been suggested to address these limitations, including the echoic mention theory (Sperber and Wilson, 1981) and its variants (Kreuz and Glucksberg, 1989; Wilson and Sperber, 1992; Sperber and Wilson, 1998), and the pretense theory (Clark and Gerrig, 1984) and its variants (Clark, 1996). However they all fail to uniquely identify sarcasm, as argued by Utsumi (2000) and Oprea and Magdy (2020).

Implicit Display Theory (IDT) Introduced by Utsumi (1996), the IDT focuses specifically on making the distinction between sarcasm and non-sarcasm. We invite the interested reader to consult (Utsumi, 2000) for an overview of how it overcomes the limitations of previous theories. We chose it as a grounding for our generation system.

The IDT first defines the concept of an ironic environment. We say a situation in which an utterance occurs is surrounded by an ironic environment if the discourse context includes the following components: (1) The speaker has expectation $Q$ at time $t_0$; (2) $Q$ fails at time $t_1 > t_0$; and (3) The speaker has a negative attitude towards the failure of $Q$. Note that the idea of linking sarcasm to an expectation is not new to Utsumi (1996), rather it is supported by previous work (Kreuz and Glucksberg, 1989; Kumon-Nakamura et al., 1995).

Next, according to the IDT, an utterance is sarcastic if and only if it implicitly displays the ironic environment. Implicit display is realised if the following linguistic devices are present in the utterance: (1) allusion to the speaker’s failed expectation $Q$; (2) pragmatic insincerity, realised by intentionally violating one of the pragmatic principles, e.g. Grice’s maxims (Grice, 1975); and (3) implication (indirect expression) of the speaker’s negative attitude towards the failure of $Q$. Finally, the theory claims that the degree of sarcasm of an utterance is proportional to how many of these linguistic devices are present in the utterance.

4 Methodology

In this section we look at the methodology employed to address our research questions. Specifically, we first select a set of input utterances. Next, for each input, we generate four sarcastic responses of different flavours using Chandler (the generation system that we suggest), and three more responses using other systems. Finally, for each input, in a survey, we ask human participants to rate the responses across several dimensions, to understand their preference towards the appropriateness of sarcasm, and which linguistic devices they associate with sarcasm.

4.1 Selecting Input Texts

As inputs, we select texts from the corpus published by Wilson and Mihalcea (2019). The corpus contains short texts (extracted from tweets) where users describe actions they performed. We compute the sentiment polarity of each text using the classifier from Barbieri et al. (2020), a RoBERTa model (Liu et al., 2019) fine-tuned on the tweet sentiment dataset from Rosenthal et al. (2017). Next, we form five partitions of 50 texts each: very negative and very positive, containing the top 50 texts based on their negative and positive probabilities, respectively; negative, containing random texts for which the probability of being negative was higher that the probabilities of being positive or neutral; and positive and neutral, partitions that we formed analogously to how we formed the negative partition. Our final input dataset contains 250 texts.

4.2 Generating Sarcastic Responses

The IDT directly suggests an algorithm for sarcasm generation that identifies an ironic environment, then creates an utterance that implicitly displays it. We now discuss how we implement each step.

Ironic Environment As discussed in Section 4.1, each input text $U_{in}$ describes an action. In this scenario, herein, we assume the expectation $Q$ that is part of the ironic environment negates that action. For instance, say $U_{in}$ expresses the event $P = \text{[user] wins the marathon}$. We assume $Q = \neg P = \text{[user] does not win the marathon}$. As we shall see, the algorithm we suggest will not, in fact, require us to formulate $Q$, but it relies on the above assumption.
Allusion to $Q$ Following Utsumi (2000), we define allusion in terms of coherence relations, similar to the relations of rhetorical structure theory (RST) (Mann and Thompson, 1987). That is, if $U_\alpha$ is an utterance that expresses proposition $\alpha$, we say $U_\alpha$ alludes to the expectation $Q$ if and only if there is a chain of coherence relations from $\alpha$ to $Q$. So, we need to first select a proposition $\alpha$ to either start or end the coherence chain, then specify the chain between $\alpha$ and $Q$, and formulate $U_\alpha$ such that it expresses $\alpha$. We suggest defining such $\alpha$ as objects of if-then relations, where the subject is $P$, the proposition expressed by input text $U_in$. That is, relations of the form “if $P$ then $\alpha$” should hold. To infer $\alpha$ given $U_in$, we use COMET (Bosselut et al., 2019), an adaptation framework for constructing commonsense knowledge. Specifically, we use the COMET variant fine-tuned on ATOMIC (Sap et al., 2019), a dataset of typed if-then relations. COMET inputs the subject of the relation, along with the relation type, and outputs the relation object. In our case, the subject is $U_in$, and we set $\alpha$ to the relation object.

In the examples that follow, assume the input text is $U_in = \langle$user$\rangle$ won the marathon’. We leverage four relation types: (1) $xNeed$: the object $\alpha$ of a relation of this type specifies an action that the user needed to perform before the event took place, e.g. “if $U_in$ then $\alpha = [xNeed to train hard]””; (2) $xAttr$: the object $\alpha$ specifies how a user that would perform such an action is seen, e.g. “if $P$ then $\alpha = [xAttr competitive]”; (3) $xReact$: the object $\alpha$ specifies how the user could feel as a result of the event, e.g. “if $P$ then $\alpha = [xReact happy]”; and (4) $xEffect$: the object specifies a possible effect that the action has on the user, e.g. “if $P$ then $\alpha = [xEffect gets congratulated]”. In Table 1 we show, for each relation type, the coherence chains between the relation object $\alpha$ and the failed expectation $Q$. Under these conditions, to generate an utterance $U_\alpha$ that alludes to $Q$, we need to choose any $U_\alpha$ that expresses $\alpha$.

Pragmatic insincerity The second requirement for implicit display is that the utterance generated should include pragmatic insincerity. In this paper, we focus on violating Grice’s maxim of quality (Grice, 1975), where we aim for the propositional content of the generated utterance to be incongruous to that of $U_in$ (input text). To achieve this, we first choose an if-then relation type, then infer the relation object $\alpha$ from $U_in$ using COMET, and construct an utterance that expresses $\neg\alpha$. For instance, if $U_in = \langle$user$\rangle$ won the marathon’, and we have chosen the $xAttr$ relation type, the constructed utterance could express $\neg\alpha = [\langle$user$\rangle$ is not competitive].

Negative attitude To fulfill the last requirement of implicit display, the utterance generated should imply a negative attitude towards the failure of the expectation $Q$. As pointed out by Utsumi (1996), this can be achieved by embedding verbal cues usually associated with such attitudes, including hyperbole and interjections.

Logical form and explainability At this point we formulate Algorithm 1 for generating a sarcastic response $U_out$, given an input utterance $U_in$ that expresses proposition $P$. We refer to $\text{emotion}(\neg\alpha)$ as the logical form of the sarcastic response we generate. Here, $\text{emotion}$ is a function that augments $\neg\alpha$ to express a negative attitude. Note that the logical form, together with the coherence chain between $\alpha$ and the failed expectation $Q$, provide a complete explanation for how and why sarcasm occurs. The explanation is $\epsilon = (\text{emotion}(\neg\alpha), C)$, where is $C$ the coherence chain from $\alpha$ to $Q$. The coherence chain for each relation type can be selected from Table 1. This makes our sarcasm generation process accountable.

Logical Form to Text To convert the logical form to text, we rely on predefined patterns for each if-then relation type. As a running example, assume the input utterance $U_in = \langle$user$\rangle$ won the marathon’ and the chosen relation type is $xAttr$. Say $\alpha = \text{COMET}(U_in, xAttr) = [xAttr competitive]$. The logical form is $\text{emotion}(\neg xAttr$ competitive$)$. We first construct an intermediate utterance $U_\alpha$ using the rule $\langle$user$\rangle$ $\langle$verb$\rangle$ competitive, where $\langle$verb$\rangle$ is a verb specific to each relation type. In our example, $U_\alpha$ could be ‘<user> is competitive’. Next, for each input $U_in$, we generate three responses. The first response $U_{out}$ only includes pragmatic insincerity, i.e. it expresses $\neg xAttr$.

Algorithm 1: Generate sarcastic response

\begin{algorithm}
\caption{Generate sarcastic response}
\label{algo:generate_sarcastic_response}
\begin{algorithmic}
  \Require utterance $U_in$.
  \Ensure ironic environment
  \Statex \quad Let $Q := \neg P$ be the failed expectation;
  \Ensure implicit display
  \Statex \quad Choose an if-then relation type $\tau$ from $xNeed$, $xAttr$, $xReact$, and $xEffect$;
  \Statex \quad Let $\alpha = \text{COMET}(U_in, \tau)$;
  \Ensure return response $U_{out}$ that expresses $\text{emotion}(\neg \alpha)$;
\end{algorithmic}
\end{algorithm}
We built three surveys, labelled (a)–(c), that we published on the Prolific Academic\(^2\) crowdsourcing platform, one for each output type, out of \(U_{\text{out}}\), competitive. To construct it, we apply a rule-based algorithm to generate the negation of \(U_{\alpha}\) in a manner similar to (Chakrabarty et al., 2020), discussed in Section 2. \(U_{\text{out}}\) could be ‘<user>’ is not competitive. The second response \(U_{\text{out}}\) does not include pragmatic insincerity, but only markers that express an emotional attitude, i.e. it expresses \(\text{emotion}(\text{xAttr competitive})\). To achieve this, in a pattern-based manner, we augment \(U_{\alpha}\) with hyperbole and interjections, as indicated by Utsumi (2000). \(U_{\text{out}}\) could be ‘<user>’ is definitely competitive, yay!’.

Table 1: Coherence chains between the object \(\alpha\) of an if-then relation and the failed expectation \(Q\), for each relation type, as discussed in Section 4.2. Here, \(P\) is the proposition expressed by the input text \(U_{\text{in}}\). In the examples, \(U_{\text{in}} = <\text{user}>\) won the marathon.

Table 2: Responses generated by all systems to the ut-terance “I ran out of characters :drooling_face:”, as discussed in Section 4.3.

In the running example we focused on the xAttr relation type. Recall there are four relation types that we consider, xNeed, xAttr, xReact, and xEffect. As such, for each input text \(U_{\text{in}}\), we generate 12 responses: three response types, \(U_{\text{out}}\), \(U_{\text{out}}^{-1}\), and \(U_{\text{out}}\), for each relation type. We use the pattern Ch-creation \(\la \ra i\ra e\ra\ra\) to refer to each response of our system, Chandler. For instance, Ch-xAttr refers to \(U_{\text{out}}\) built considering the xAttr relation, while Ch-xNeed\(^{-1}\) refers to \(U_{\text{out}}\) built considering the xNeed relation.

Table 2: Responses generated by all systems to the utterance “I ran out of characters :drooling_face:”, as discussed in Section 4.3.

In each survey, we also enclosed a response from DialoGPT (Zhang et al., 2020), a recent dialogue system that is not built to be sarcastic; a response produced by SarcasmBot, the sarcastic response generator of Joshi et al. (2015) ; and a response produced by \(R^{3}\), the state-of-the-art sarcastic paraphrase generator of Chakrabarty et al. (2020). Note that \(R^{3}\) is designed to produce rephrases. As such, we applied \(R^{3}\) to the output of DialoGPT to get a sarcastic rephrase of a response to the input. Table 2 shows an example input utterance, along with responses from all systems.

All in all, each survey instance contained a specific input text, and seven responses generated as mentioned above and presented in a random order. In the survey, we asked participants to evaluate each response across four dimensions: (1) Sarcasm:
We noticed a few main themes, that we labelled "joke", "family", "school", "leisure" and "death". We then asked two humans to label all inputs across these dimensions. A third human resolved all disagreements. Finally, we computed the Pearson correlation coefficient of each theme with the sarcasm appropriateness score, across all inputs. We noticed a significant ($p < 0.05$) positive correlation between appropriateness and the category "joke", and significant negative correlation with belonging to the "family" theme. We show some examples of the theme "family" with low appropriateness scores in Table 3.

Thus, according to our analysis, sarcasm seems to be most appropriate for positive inputs, and for humorous inputs, which may invite more sarcastic responses. In other situations, however, sarcasm might be interpreted as inappropriate and even offensive (Meaney et al., 2021).

### 5.1.2 When is sarcasm preferred?

We first consider the overall preference towards either sarcasm or non-sarcasm. Recall that participants also specified their preferred response for each input. The distribution of the sarcasm, humour, specificity, and coherence scores of this preferred response, across all survey instances, is illustrated in Figure 2 with a blue, continuous, line. The red, dashed, line illustrates the distribution across highest and lowest appropriateness scores, respectively.

<table>

</tr>
</tbody>
</table>
the 80 survey instances where the sarcasm appropriateness score of the input was higher than the midpoint, i.e. at least 3.

We notice considerably higher preference towards non-sarcastic and non-humorous responses. As indicated by the blue lines, over 50% of the preferred responses were those considered non-sarcastic and non-humorous by participants, the rest of the distribution being highly skewed towards the lower sarcasm and humour regions. Furthermore, note that even when sarcasm was considered highly appropriate, participants still preferred non-sarcastic responses, as indicated by the red, dashed, line in the top-left of Figure 2. Although there is a shift in the distribution towards sarcasm in this case, the skew is still towards the non-sarcastic region. Looking at the bottom row of Figure 2, on the other hand, we notice a negative skew, indicating an overall preference towards higher coherence. This is slightly the case for specificity as well.

To investigate further, we fit a logistic regression model to predict whether a response is preferred based on its sarcasm, humour, specificity, coherence scores, and two-way interactions between these variables. All coefficients are listed in Appendix B. We noticed a significant ($p < 0.05$) positive relationship between coherence and preference, as well as the interaction between sarcasm and humour. The term representing the product of sarcasm and specificity had a significant negative effect on preference. In terms of the specific systems, we notice DialoGPT was preferred about 44% of the time, followed by Ch-xAttr$^{-1}$ (20%), and SarcasmBot (15%), which corresponds exactly to the coherence ranking in Table 4.

Our results indicate that responses with high coherence to the inputs are generally preferred over sarcastic responses. Sarcasm is only preferred when it is also considered humorous. On the other hand, participants seem to have actively avoided sarcastic responses that were very specific.

5.2 RQ2: How Should a Bot Formulate Sarcasm

5.2.1 Linguistic Devices

In Table 4 we show mean sarcasm, humour, specificity, and coherence scores provided by participants for each variant of Chandler, across all inputs. In the table, there are four groups (1–4) and three systems within each group (a–c). Rows with index (a) show scores for the complete versions of Chandler, for each if-then relation type. Rows (b) and (c) show partial versions, omitting pragmatic insincerity and emotional markers, respectively.

**Table 4:** Means of the sarcasm, humour, specificity, and coherence scores provided by participants, for each variant of Chandler (Ch). "∗∗" indicates statistically significant difference from row (a) within the same numbered group (t-tests with Bonferroni correction, $p < 0.001$).

As indicated by the blue lines, over 50% of the preferred responses were those considered non-sarcastic and non-humorous by participants, the rest of the distribution being highly skewed towards the lower sarcasm and humour regions. Furthermore, note that even when sarcasm was considered highly appropriate, participants still preferred non-sarcastic responses, as indicated by the red, dashed, line in the top-left of Figure 2. Although there is a shift in the distribution towards sarcasm in this case, the skew is still towards the non-sarcastic region. Looking at the bottom row of Figure 2, on the other hand, we notice a negative skew, indicating an overall preference towards higher coherence. This is slightly the case for specificity as well.

To investigate further, we fit a logistic regression model to predict whether a response is preferred based on its sarcasm, humour, specificity, coherence scores, and two-way interactions between these variables. All coefficients are listed in Appendix B. We noticed noticed a significant ($p < 0.05$) positive relationship between coherence and preference, as well as the interaction between sarcasm and humour. The term representing the product of sarcasm and specificity had a significant negative effect on preference. In terms of the specific systems, we notice DialoGPT was preferred about 44% of the time, followed by Ch-xAttr$^{-1}$ (20%), and SarcasmBot (15%), which corresponds exactly to the coherence ranking in Table 4.

Our results indicate that responses with high coherence to the inputs are generally preferred over sarcastic responses. Sarcasm is only preferred when it is also considered humorous. On the other hand, participants seem to have actively avoided sarcastic responses that were very specific.

5.2 RQ2: How Should a Bot Formulate Sarcasm

5.2.1 Linguistic Devices

In Table 4 we show mean sarcasm, humour, specificity, and coherence scores provided by participants for each variant of Chandler, across all inputs. In the table, there are four groups (1–4) and three systems within each group (a–c). Rows with index (a) show scores for the complete versions of Chandler, for each if-then relation type. Rows (b) and (c) show partial versions, omitting pragmatic insincerity and emotional markers, respectively.

**Table 4:** Means of the sarcasm, humour, specificity, and coherence scores provided by participants, for each variant of Chandler (Ch). "∗∗" indicates statistically significant difference from row (a) within the same numbered group (t-tests with Bonferroni correction, $p < 0.001$).

impacted by the omission of emotional markers for all relation types considered except for xEffect (row 4). Oh the other hand, coherence and specificity are not significantly influenced.

To sum up, the degree of perceived sarcasm is influenced by all linguistic devices considered. Out of the if-then relation types we consider, mentioning attributes of the user seems to lead to the highest perceived sarcasm, humour, specificity and coherence. Being insincere about the state of affairs leads to significantly higher perceived sarcasm, but significantly lower specificity and coherence. Emotional markers increase sarcasm and humour perception, but do not significantly impact specificity or coherence. Finally, recall that a main claim of IDT was that the degree of sarcasm of an utterance grows with the number of implicit display conditions met. Our results support this claim.

5.2.2 Preferred Flavour

While we established that participants typically preferred non-sarcastic responses, we next set out to find what sarcasm people preferred in our experiments when they did prefer sarcasm. To do this, we consider the set of survey instances that showed the complete versions of Chandler, where the sarcasm score given by the participant to their preferred response was at least 3, leaving us with 107 (around 14%) of the 750 survey instances. We divide these instances into five categories, based on input sentiment. Within each category, for each generation system, we count the number of times that a response produced by that system was preferred. Figure 3 shows the normalised counts across all systems, for each sentiment category.

We observe that, for positive inputs, where sarcasm was considered significantly more appropriate than other sentiment categories, people prefer responses produced by Ch-xNeed. Interestingly, however, we observe that people prefer the fairly nonspecific, pattern-based sarcastic remarks produced by SarcasmBot for most types of input text. However, when analysing its outputs, we noticed it produced a total of only 28 unique responses (listed in Appendix C) to our 250 inputs. While in our experiments each response was only shown at most three times, in a real scenario of a user interacting with a conversational agent, the user might not appreciate repeatedly receiving the same response.

6 Recommendations

We recommend that future work on sarcasm generation should account for the four main findings:

(1) People think sarcasm is inappropriate as a response to most inputs. However, if it is to be used, it is seen as most appropriate when the input is positive, but not extremely positive. People also found sarcasm to be a suitable response to jokes.

(2) Even when deemed appropriate, people usually do not prefer sarcasm. Rather, coherence is the most important factor in explaining their response preferences. When people do prefer sarcasm, they like it mainly when it is also seen funny. Further, they generally dislike sarcasm that is very specific.

(3) When generating sarcasm, pragmatic insincerity and emotional markers are important to include as they have a high influence of sarcasm perception.

(4) Overall, people commonly prefer the simple general sarcastic responses of SarcasmBot, even compared to more sophisticated generation models, which suggests that presently, a simpler solution to sarcasm generation may actually be advantageous. Nevertheless, more investigation is required to examine if it will be desirable in long conversations, since it has limited diversity in outputs.

7 Conclusion

We have presented a linguistically informed framework for sarcasm generation so that we could present human judges with a variety of flavors of sarcastic responses in a range of situations. Our findings suggest that sarcasm should not always be generated, but the decision to generate sarcasm itself should be informed by user preferences. People find sarcasm most appropriate as a response to positive utterances and cases in which a joking environment has already been established. Further, judges preferred sarcasm most when they actually found it to be funny, and most often preferred general sarcastic responses. However, people often preferred non-sarcastic responses even more. We recommend that future work in this area carefully considers both the appropriateness and necessity of generating sarcasm at all.
8 Ethical Considerations

In our experiments, we noticed that some of the input tweets contained references to sensitive topics, such as religion and gender, or to tragic life events (e.g., death). Producing sarcasm for such inputs might be inappropriate and offensive to some (as our experiments confirmed). We clearly informed our survey participants about this possibility in the Participant Information Sheet, before accessing our survey. The sheet is enclosed in Appendix D.

A Logical Form to Text Patterns

In this section we show the patterns used by Chandler to convert the logical form of sarcasm to text, as discussed in Section 4.2 of the main paper. We show patterns for each if-then relation type, xNeed, xAttr, xReact, and xEffect.

In the patterns below, <inten> is an intensifier, <suff_inten> is an intensifier added at the end of a phrase, <pos> is a positive emotion word, and <interr> an interjection. Inspired by (Utsumi, 2000) and (Joshi et al., 2015), each of these were randomly chosen from the following sets:

- <inten> : [very]
- <suff_inten> : [for sure]
- <pos> : [Good job, Well done]
- <interr> : [Yay!, Brilliant!]!

xObt below is the object of the corresponding if-then relation object, as provided by COMET when taking in the input tweet.

A.1 Patterns for the Complete Version of Chandler

xNeed patterns:
- You didn’t <obt>, that’s <suff_inten> <pos>!

xAttr patterns:
A.2 Patterns for Chandler without Pragmatic Insincerity

xReact patterns:
• You’re not feeling <inten> <obt> right now, that’s <suff_inten> . <interj>

xEffect patterns:
• You’re not going to obt_inf right now, that’s <suff_inten> . <interj>

A.3 Patterns for Chandler without Emotional Markers

xNeed patterns:
• You didn’t <obt>.

xAtrr patterns:
• You’re not <obt>.
• You’re not a <obt> person.

xReact patterns:
• You’re not feeling <obt> right now.

xEffect patterns:
• You’re not going to obt_inf right now.

B Logistic Regression Coefficients

In Table 5 we present the full model parameters for the logistic regression experiment from section 5.1.2.

C SarcasmBot Outputs

We noticed SarcasmBot produced a total of only 28 unique responses to our set of 250 inputs, as discussed in Section 5.2.2 of the main paper.

D Participant Information Sheet

D.1 What will I do?

Imagine someone (we’ll call them PersonX), makes a statement. You will be shown a few responses to that statement. The responses were generated by chatbots (computer programs). Some sentences talk about sensitive topics, such as tragic life events. Responses to such sentences could be potentially inappropriate, or even offensive or harmful. Unfortunately, chatbots do not understand whether or not a topic is sensitive for a human. Please be fully aware of this when accepting to take part in our
study.
For each response, you will be asked:

1. How sarcastic you find the response? (0 - not sarcastic, 3 - very sarcastic)
2. How funny you find the response? (0 - not funny, 3 - very funny)
3. How specific is the response to PersonX’s statement? The response is specific if it mentions details that show a good understanding of PersonX’s statement and its implications. Otherwise it’s general. (0 - very general, 3 - very specific).
4. How coherent is the response to PersonX’s statement? The response is coherent if it makes sense as a response. That is, it’s a clear and sensible response that someone might actually give. It does not matter if it’s specific or general. (0 - not coherent, 3 - very coherent).

Let’s take a quick example. In this example, imagine that PersonX’s statement is “I went to the grocery store”. Here are some responses about this statement.

About being specific:

- "That’s great." - Very general response. You can say this as a response to pretty much anything.
- "Nice to hear you are enjoying this sunny day." - General response. It does provide some details about the day (that it’s sunny). However, those details are not uniquely related to PersonX’s statement.
- "You must be tired." - More specific response. It shows an understanding that going somewhere (anywhere at all) may cause tiredness.
- "You probably bought a lot of vegetables." - Specific response. It shows an understanding of what a grocery store is. That is, a place where you can probably buy vegetables.
- "You must have been quite hungry for carrots." - Very specific response. It shows an understanding of what a grocery store is, about what carrots are, and about the link between carrots and the store (mainly, that carrots are sold there).

About being coherent:

- "I’m cold." - Not coherent. It has nothing to do with PersonX’s statement.
- "I went to the grocery store". It’s not a suitable response that someone would normally give.
- "I had such a wonderful dream last night, there were a lot of awesome cars painted blue." - Not coherent. It does not make sense as a response to PersonX’s statement.
- "I sometimes dream about eating carrots." - More coherent response. Someone might sometimes say this as a response, although it’s not a common response.
- "OK thanks." - Very coherent. One might actually say this as a response. Notice it’s not specific to PersonX’s statement. You can say it as a response to many other statements. Still, it’s coherent to PersonX’s statement. Thanks a lot for getting me those carrots, I’ll pay you back next week. - Very coherent and very specific to PersonX’s statement.

D.2 Participant Information Sheet and Consent Form

- Principal investigator: [our PI’s name]
This study is in the process of being certified according to the details about the ethics committee of our institution. Please take time to read the following information carefully. You should keep this page for your records.

D.3 Who are the researchers?
We are the group, a research group that brings together a range of researchers from our institution in order to build on our existing strengths in social media research. The principal investigator is our PI’s name.

D.4 What is the purpose of the study?
This study aims to understand what linguistic style people associate with sarcasm.

D.5 Why have I been asked to take part?
We target everyone registered as living in country on the Prolific Academic platform.

D.6 Do I have to take part?
No—participation in this study is entirely up to you. You can withdraw from the study at any time, without giving a reason. Your rights will not be affected. If you wish to withdraw, contact the PI. We will stop using your data in any publications or presentations submitted after you have withdrawn consent. However, we will keep copies of your original consent, and of your withdrawal request.

D.7 What will happen if I decide to take part?
You will be asked to fill in a survey. The flow of the survey is the following:

- You will be shown 7 responses to the text that you selected;
- For each response, you will be asked to specify, on a scale from 1 to 5: (a) How sarcastic it is; (b) How funny it is; (c) How coherent it is to the original text; It is coherent if it sounds like a reasonable response that a person might give. (d) How specific it is to the original text; It is specific if it mentions details about the original text, or its implications, that make this response not appropriate as a response to many other texts.

We estimate it will take around 3 minutes to complete the survey.

D.8 Compensation
You will be paid £0.38 for your participation in this study.

D.9 Are there any risks associated with taking part?
Please note: some of the texts that you will see include content that you might consider sensitive, or might trigger unwanted memories. For instance, they might mention losing a family member, losing friends, break-ups, failure in exams, or health issues.

D.10 Are there any benefits associated with taking part?
Financial compensation of £0.38.

D.11 What will happen to the results of this study?
The results of this study may be summarised in published articles, reports and presentations. Quotes or key findings will be anonymized: We will remove any information that could, in our assessment, allow anyone to identify you. With your consent, information can also be used for future research. Your data may be archived for a minimum of 2 years.

D.12 Data protection and confidentiality
Your data will be processed in accordance with Data Protection Law. Throughout your entire interaction with us, the only information collected about you specifically is your Prolific Academic identification number. This data will only be viewed by the team members of the group, listed here:
(our group’s website). All other data, including the responses you provide, and the amount of time you took to fill in the survey, will be made public on the internet as part of Open Science, available to be indexed by search engines. The Open Science initiative is described here: https://en.wikipedia.org/wiki/Open_science.

D.13 What are my data protection rights?

(our institution) is a Data Controller for the information you provide. You have the right to access information held about you. Your right of access can be exercised in accordance Data Protection Law. You also have other rights including rights of correction, erasure and objection. However, we will have no control for the data that will be made public, as specific in the previous section. For more details, including the right to lodge a complaint with the Information Commissioner’s Office, please visit (website of the Data Protection officer). Questions, comments and requests about your personal data can also be sent to (the data protection officer at our institution). For general information about how we use your data, go to: (website with information on research privacy at our institution).

D.14 Who can I contact?

If you have any further questions about the study, please contact the lead researcher, (lead researcher’s name and email address). If you wish to make a complaint about the study, please contact (email address of the ethics committee at our institution). When you contact us, please provide the study title and detail the nature of your complaint.

D.15 Updated information

If the research project changes in any way, an updated Participant Information Sheet will be made available on (website where updates are published).

D.16 Consent

By proceeding with the study, you agree to all of the following statements:

- I have read and understood the above information.

- I understand that my participation is voluntary, and I can withdraw at any time.

- I consent to my anonymised data being used in academic publications and presentations, as well as published publicly on the internet, as part of Open Science.

- I am aware that I will see potentially offensive, harmful, or hurtful content.

- I allow my data to be used in future ethically approved research.
