# Fact-Level Confidence Calibration: Empowering Confidence-Guided LLM Self-Correction

Anonymous ACL submission

#### Abstract

 Confidence calibration in LLMs, i.e., align- ing their self-assessed confidence with the ac- tual accuracy of their responses, enabling them to self-evaluate the correctness of their out- puts. However, current calibration methods for LLMs typically estimate two scalars to represent overall response confidence and cor- rectness, which is inadequate for long-form generation where the response includes mul- tiple atomic facts and may be partially confi- dent and correct. These methods also overlook the relevance of each fact to the query. To address these challenges, we propose a Fact- Level Calibration framework that operates at a finer granularity, calibrating confidence to relevance-weighted correctness at the fact level. Furthermore, comprehensive analysis under the framework inspired the development of Confidence-guided Fact-level self-correction (ConFact), which uses high-confidence facts within a response as additional knowledge to improve low-confidence ones. Extensive ex- periments across four datasets and six mod- els demonstrate that ConFact effectively miti-025 gates hallucinations without requiring external 026 **howledge sources such as retrieval systems<sup>[1](#page-0-0)</sup>.** 

#### 027 1 Introduction

 Large Language Models (LLMs) have re- cently achieved notable breakthroughs in various tasks [\(Brown et al.,](#page-8-0) [2020\)](#page-8-0), demonstrating their ability to comprehend and generate language that bears a striking resemblance to human communica- tion [\(OpenAI,](#page-9-0) [2023\)](#page-9-0). Nonetheless, a major obstacle to their reliability is the prevalence of hallucina- tions [\(Lin et al.,](#page-9-1) [2021;](#page-9-1) [Zhang et al.,](#page-9-2) [2023;](#page-9-2) [Li et al.,](#page-8-1) [2023a;](#page-8-1) [Golovneva et al.,](#page-8-2) [2022;](#page-8-2) [Bang et al.,](#page-8-3) [2023\)](#page-8-3), a phenomenon where the models generate incorrect and unreliable outputs. This issue not only under-mines user trust but also restricts the application of

<span id="page-0-1"></span>

Figure 1: Motivation of our fact-level confidence calibration and confidence-guided self-correction.

LLMs in domains where reliability is crucial, such **040** as in the legal, financial, and educational fields. **041**

Echoing the ancient adage that *"To know what* **042** *you know and what you do not know, that is true* **043** *wisdom"*, confidence calibration in LLMs emerges **044** as an effective approach to mitigate the issue of hal- **045** [l](#page-8-4)ucinations [\(Li et al.,](#page-9-3) [2024;](#page-9-3) [Liu et al.,](#page-9-4) [2023;](#page-9-4) [Huang](#page-8-4) **046** [et al.,](#page-8-4) [2024\)](#page-8-4). By confidence calibrating, models **047** can better align their self-assessed confidence with **048** the actual accuracy of their responses, empowering **049** them to self-evaluate the correctness of their out- **050** puts. This mechanism offers an effective way to **051** identify hallucinations by using the model's confi- **052** dence as a basis for users to either trust or question **053** the model's response. **054**

However, current confidence calibration meth- **055** [o](#page-9-5)ds for LLMs [\(Guo et al.,](#page-8-5) [2017a;](#page-8-5) [Nguyen and](#page-9-5) **056** [O'Connor,](#page-9-5) [2015\)](#page-9-5) typically estimate two scalars to **057** represent the overall confidence and correctness for **058** the entire response. This approach is unreasonable **059** for long-form generation, where responses may **060** contain multiple atomic facts (illustrated in Fig[.1\)](#page-0-1). **061** In such cases, considering the varying of facts **062** in one response, the confidence and correctness **063**

<span id="page-0-0"></span> ${}^{1}$ Code is available at [https://anonymous.4open.](https://anonymous.4open.science/r/fact-cal-correct) [science/r/fact-cal-correct](https://anonymous.4open.science/r/fact-cal-correct)

 should also be diverse, capable of reflecting higher certainty in some facts and greater uncertainty in others. Furthermore, within long-form responses, certain facts exist that may indeed be correct but lack relevance to the query. Previous calibration methodologies predominantly focus on assessing correctness while neglecting to incorporate consid-erations of relevance.

 To address these challenges, we propose a novel framework for confidence calibration operating at a finer fact-level granularity. Within this framework, 075 the confidence assessment of each fact incorpo- rates two key aspects: correctness and relevance. Correctness indicates the factual accuracy of the fact, while relevance measures the extent to which the fact is related to the query. Calibration of a response is defined as the degree of alignment be- tween confidence and correctness weighted by rele- vance across all facts. This framework endows the model with the capability to exhibit partial confi- dence and correctness in individual facts. Extensive analysis based on the aforementioned framework yields three interesting findings: (1) fact-level cali- bration imposes a stricter standard than response- level calibration. (2) fact-Level can mitigate over- confidence issues. (3) the variance in confidence distribution among different facts within the same response is considerable.

 The aforementioned three observations inspire the development of Confidence-Guided Fact-Level Self-Correction (ConFact) to enhance the gen- eration and mitigate hallucinations (illustrated in Fig[.1\)](#page-0-1). For a response, ConFact first leverages the aforementioned framework to segment the re- sponse into multiple facts and evaluate their confi- dence vector. It then uses the high-confidence facts and their associated confidence score as additional knowledge to augment low-confidence facts, with the aim of all facts within the response achieving high confidence. ConFact can self-enhance to mit- igate hallucinations without the need for external knowledge sources such as retrieval systems. Ex- periments with ConFact across four datasets and six models reveal that it can significantly reduce the occurrence of hallucinations, thereby increasing the models' reliability and enabling their practical application in real-world scenarios.

**111** Our main contributions include:

**112** • Fact-Level Calibration Framework: The **113** proposed fact-level calibration framework op-**114** erates at a finer level of granularity to align the

confidence with the correctness weighted by **115** relevance across all facts. This framework en- **116** dows the model with the capability to exhibit **117** partial confidence and correctness in individ- **118** ual facts. **119** 

- Insightful Observations: We uncover insight- **120** ful observations regarding the model's scale **121** and its calibration capability. **122**
- Self-Correction Method: We propose **123** ConFact method based on the fact-level cali- **124** bration framework to enhance the generation **125** and reduce hallucinations without relying on **126** external knowledge sources. **127**

# 2 Preliminary and Problem Formulation **<sup>128</sup>**

#### 2.1 Preliminary **129**

Consider a dataset defined as  $D = 130$  $\{x_1, x_2, \ldots, x_N\}$ , where  $x_i$  denotes the *i*-th 131 query, with a total count of N queries. Let the **132** model's responses to queries be represented as **133**  $A = {\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_N}$ , where each  $(\mathbf{x}_i, \mathbf{y}_i)$  forms 134 a query-answer pair. The confidence  $\text{conf}_i$  signifies the model's degree of certainty in its answer  $y_i$  **136** to the query  $x_i$ . The correctness  $corr_i$  measures 137 the objective truthfulness of the response  $y_i$  to **138** the query  $x_i$ . The aim of confidence calibration 139 is to ensure that, for every confidence interval, **140** the average confidence of the query-answer pairs **141** within that interval aligns with their average 142 correctness. **143**

#### 2.2 Problem Formulation **144**

Considering the long-form generation nature of **145** LLMs, our proposed confidence calibration is de- **146** fined at a fact-level granularity, where both the **147** correctness and relevance of each fact will be con- **148** sidered. We define the problem as follows: dif- **149** ferent from the traditional definition of confidence **150** calibration, we assume the response  $y_i$  contains  $151$  $M_i$  facts represented as  $\{f_i^j\}$  $\begin{bmatrix} i^j \\ i \end{bmatrix}$   $\begin{bmatrix} M_i \\ j=1 \end{bmatrix}$ . Each fact  $f_i^j$  will 152 be evaluated with a relevance value  $rel_i^j$  and a correctness value  $corr_i^j$  $i<sup>j</sup>$ . Meanwhile, this fact is also **154** associated with a confidence score  $conf_i^j$  representing the LLM's level of uncertainty regarding that **156** fact. The goal of fact-level calibration is to align **157** the confidence with the relevance-weighted correct- **158** ness in terms of the response  $y_i$  across  $M_i$  facts. 159

# **<sup>161</sup>** 3 Fact-Level Confidence Calibration

 In this section, we begin by presenting our moti- vation and offering a detailed introduction to the architecture of Fact-Level Confidence Calibration framework. Subsequently, we delve into three in- triguing observations within our framework. Fi- nally, we summarize how these observations in-spire our approach to self-correction.

# **169** 3.1 Motivation

 Compared to the confidence calibration for short- form generation or traditional classification prob- lems, a significant challenge in calibrating long- form text generation is that a response may contain multiple facts, making it unreasonable to assign a single correctness measure and a single confidence score to the entire response. The reason is that the answer might be partially correct, and the model might also be partially confident in only a subset of the facts of a response. Meanwhile, some facts in response are irrelevant to the query, so the cali-bration based solely on correctness is insufficient.

 Based on the above motivation, our proposed cal- ibration framework aims to calibrate the confidence to relevance-weighted correctness on the fact level, which leads to the following two advantages: (1) **Finer Granularity:** we assign a confidence vec- tor rather than a scalar to a response, where each item represents confidence for a single fact. This fine-grained framework allows for more nuanced and precise calibration. (2) Relevance Awareness: we assess both the correctness and the relevance of each fact, which ensures that the confidence score attributed to each fact can reflect its significance and appropriateness within the given context.

# <span id="page-2-1"></span>3.2 Architecture **195**

To calibrate the confidence with the relevance- **196** weighted correctness on the fact level, our frame- **197** work includes four components as illustrated **198** in fig. [2:](#page-2-0) fact extraction, correctness and relevance **199** evaluation, confidence estimation, and evaluation **200** based on fact-level calibration metric. **201**

Fact Extraction Given a query-answer pair **202**  $(\mathbf{x}_i, \mathbf{y}_i)$  from a model to be calibrated, we first dissect the response to identify the contained facts. 204 This process can be performed by a powerful ex- **205** ternal language model (e.g., GPT-4 [\(Brown et al.,](#page-8-0) **206** [2020\)](#page-8-0)), resulting in a set of facts  $\{f_i^j\}$  $\{i^j\}_{j=1}^{M_i}$  for the **207** response  $y_i$ . . **208**

Correctness and Relevance Evaluation After **209** extracting facts, this component aims to assess **210** the correctness and relevance of each fact to the **211** query. The correctness of each fact is evaluated **212** for its factuality using GPT models in conjunction **213** with retrieval methods based on search engines 214 and the ground truth answers in datasets to obtain **215**  $\{corr_i^j$  $i$ ;  $\overline{j}$ <sub>j=1</sub>. The relevance  $\{rel_i^j\}_{j=1}^{M_i}$  of each fact 216 is also obtained based on GPT models, represent- **217** ing its pertinence to the query within the context of **218** the response. **219** 

Confidence Estimation The confidence estima- **220** tion measures the confidence of the targeted LLM **221** for each fact, considering both its correctness **222** and relevance. To obtain a confidence vector **223**  $\{conf_i^j\}_{j=1}^{M_i}$  for each response, a verbalizationbased method [\(Tian et al.,](#page-9-6) [2023\)](#page-9-6) is employed, **225** where the model is prompted to provide a confi- 226 dence score for each fact within response. Confi- **227**

228 dence of a fact  $fact_i^j$  can be represented as:

229 
$$
conf_i^j = \mathcal{C}(LLM(\cdot), p_c(f_i^j, \mathbf{x}_i, \mathbf{y}_i)),
$$
 (1)

230 where  $p_c$  is the prompt, which includes: (1) A clear task description. (2) The criteria to give confidence scores. (3) Several instances containing the input query, the complete response, one extracted fact, the associated confidence score with an explana- tion. (4) The task containing the input query, the complete response, and the target fact. The model is expected to output its confidence for the target fact in a verbalization manner, accompanied by an explanation. For a detailed prompt template, please refer to Appendix [C.](#page-10-0)

<span id="page-3-2"></span>**241** Evaluation based on Fact-level Calibration Met-

 ric We define F-ECE (Fact-Level Expected Cal- ibration Error) as the evaluation metric that quan- tifies the discrepancy between confidence and the relevance-weighted correctness across all re- sponses and their respective facts. For each fact within a response, we compute the relevance- weighted correctness as the product of the fact's correctness score and its relevance score. Response- level relevance-weighted correctness and confi- dence are then determined by averaging these relevance-weighted correctness scores and the con- fidence scores across all facts within each response, as shown in eq. [\(2\)](#page-3-0).

<span id="page-3-0"></span>
$$
re\text{-}corr_i = \frac{1}{M} \sum_{j=1}^{M} corr_i^j \times rel_i^j,
$$
\n
$$
conf_i = \frac{1}{M} \sum_{j=1}^{M} conf_i^j,
$$
\n(2)

**256** where recorr denotes the relevance-weighted cor-**257** rectness and conf denotes the confidence.

 F-ECE is finally calculated by the average relevance-weighted correctness and confidence of responses in bin k, where B is the number 261 of bins for grouping confidence scores, and  $B_k$  is the set of responses in the k-th bin. Let  $\overline{re\text{-}corr}_k = \frac{1}{|B|}$  $\overline{re\text{-}corr}_k = \frac{1}{|B_k|} \sum_{i \in B_k} corr_i$  and  $\overline{conf}_k =$ 1  $\frac{1}{|B_k|}\sum_{i\in B_k} conf_i,$ 

$$
F\text{-}ECE = \sum_{n=1}^{N} \frac{|B_k|}{N} \left| \overline{re\text{-}corr}_k - \overline{conf}_k \right| \quad (3)
$$

#### <span id="page-3-3"></span>3.3 Key Observations **266**

This section discusses three important phenom- **267** ena observed under our fact-level calibration.These **268** findings not only demonstrate the superiority of **269** our framework over traditional response-level **270** calibration, but also inspire the development **271** of a confidence-guided fact-level self-correction **272** method based on these insights. **273**

Observation 1: Fact-level calibration imposes a **274** stricter standard than response-level calibration. **275** As illustrated in fig. [3,](#page-3-1) by comparing the histogram **276** between the left side and right side, it is evident **277** that our fact-level framework can accentuate the **278** differences in calibration performance across differ- **279** ent scale models with various capabilities. Specif- **280** ically, the models (e.g., Llama-2-7b) that appear **281** well-calibrated under traditional response-level per- **282** form worse in fact-level calibration. This capabil- **283** ity stems from fact-level calibration, which takes **284** into account the fine-grained correctness at the fact **285** level and considers the relevance of each fact to **286** the query, highlighting the importance of utilizing **287** a more granular calibration assessment to uncover **288** hidden deficiencies in model performance. **289**

Observation 2: Fact-Level Can Mitigate Over- **290** Confidence Issue The distribution of confidence **291** across datasets is illustrated in fig. [4.](#page-4-0) The response- **292** level calibration assigns a single confidence value **293** to the entire response, shown in gray. In contrast, **294** our fact-level method assigns a confidence value **295** to each fact within the response, resulting in a con- **296** fidence vector for one response. We calculate the **297** mean, minimum, and maximum values of each **298** confidence vector, and depict the statistical distribu- **299**

<span id="page-3-1"></span>

Figure 3: Comparison of calibration measures between fact-level and response-level based on models with three different scales: Llama-7B, Llama-13B, and GPT-3.5.

<span id="page-4-0"></span>

Figure 4: Comparison of across-responses confidence distribution between fact-level and response-level.

<span id="page-4-1"></span>

Figure 5: Confidence distribution within responses at the fact level, the red bar is the response-level score.

 tions of these values across all responses via violin plot [\(Hintze and Nelson,](#page-8-6) [1998\)](#page-8-6). Two intriguing phenomena can be observed: (1) The confidence distribution of the response-level is narrow and centered around a high confidence value. Our dis- tribution of mean confidence values, on the other hand, is wider and shows a lower response level. (2) The distribution of the response-level is highly similar to the distribution of the maximum confi-dence values in our fact-level method.

 These two phenomena suggest that response- level confidence is dominated by the fact in the response with implicitly highest confidence, which can lead to over-confidence. Our framework, by breaking down the facts and evaluating confidence individually, can explicitly emphasize less confi- dent aspects within the response, thereby mitigat-ing the over-confidence issue.

 Observation 3: High Variance exists in Fact- level Confidence within a Response fig. [5](#page-4-1) illus- trates the distribution of confidence levels for facts within specific responses, depicted by the green box plots. The red dots represent the response-level confidence for the entire response. Two phenomena can be observed: (1) Fact-level confidence varies significantly within individual responses, while response-level confidence is relatively concentrated at a higher level. (2) Outlier facts tend to exhibit lower confidence levels. The numerous white dots in the box plots indicate the presence of these out- liers, which typically correspond to facts with sig- nificantly lower confidence scores, generally falling below the overall distribution. This suggests that

certain facts within a response are generated with **333** considerably less confidence by the model. **334**

# 4 **ConFact**: Confidence-Guided **<sup>335</sup>** Fact-Level Self-Correction **<sup>336</sup>**

In this section, we introduce the motivation and **337** architecture of Confidence-guided Fact-level self- **338** correction, dubbed **ConFact**. ConFact utilizes **339** facts with high confidence as references to revise **340** facts with low confidence, thereby enhancing the **341** generation process and mitigating hallucinations. **342** ConFact operates in real-time during the gener- **343** ation process, avoiding the need for fine-tuning **344** or training, thereby lowering costs and increasing **345** flexibility. Moreover, it does not rely on external **346** knowledge, significantly enhancing its universality. **347**

### 4.1 Motivation **348**

The development of Confidence-Guided LLM Self- **349** Correction is inspired by the aforementioned three **350** observations. The rationale behind these observa- **351** tions supporting Self-Correction lies in: (1) Our **352** observations 1 and 2 show that even under strict **353** conditions, the fact-level framework can reduce **354** over-confidence and improve the model's calibra- **355** tion, aligning confidence more closely with accu- **356** racy. This improved calibration is essential for ef- **357** fective confidence-guided self-correction. (2) Our **358** observation 3 shows that high-confidence and low- **359** confidence facts often coexist within the same re- **360** sponse. Even when confidence levels are generally **361** consistent, outliers tend to be lower confidence **362** facts. This allows high-confidence facts to pro- **363** vide the necessary knowledge to correct the low- **364** confidence ones. **365**

# 4.2 Architecture **366**

The overall architecture of ConFact is illustrated **367** in fig. [6.](#page-5-0) As can be seen, ConFact includes three **368** steps: fact extraction and confidence estimation, **369** factor extraction and fact correction, and fact confi- **370** dence re-estimation. 371

Step 1: Fact Extraction and Confidence Estima- **372 tion** Given a response  $y_i$ , ConFact first conducts  $373$ fact extraction and confidence estimation for each **374** extracted fact, following the same process as de- **375** scribed in section [3.2.](#page-2-1) After obtaining the facts **376**  $\{f_i^j$  $\sum_{i=1}^{j} M_i$  for  $y_i$  and their corresponding confidence 377 scores  $\{conf_i^j\}_{j=1}^{M_i}$ , we then split the facts into 378 two groups: high-confidence and low-confidence, **379** based on a confidence threshold  $\tau$ . **380** 

<span id="page-5-0"></span>

Figure 6: An illustration of our confidence-guided fact-level self-correction framework.

 The high-confidence group in eq. [\(4\)](#page-5-1) is used as a form of internal knowledge base, whose knowledge is leveraged to reinforce and augment facts within the low-confidence group in eq. [\(5\)](#page-5-2),

$$
f_h = \{f_i^j \mid conf_i^j \ge \tau\} \tag{4}
$$

$$
f_l = \{ f_i^j \mid conf_i^j < \tau \},\tag{5}
$$

**387** where the threshold is defined as the mean confidence score across facts  $\tau = \frac{1}{M}$ 388 **dence score across facts**  $\tau = \frac{1}{M_i} \sum_{j=1}^{M_i} conf_i^j$ .

 Step 2: Factor Extraction and Fact Correction To ensure that only the erroneous parts of the low- confidence facts are modified without changing the overall meaning, we restrict the modifiable parts. Specifically, we first parse the key factors through factor extraction. Let  $\{fa_i^{j,k}\}_{k=1}^{K_i^j}$  represent the  $K_i^j$ i factors extracted from the target fact  $f_i^j \in f_l$ ,

**394**

396 
$$
{f a_i^{j,k} \}_{k=1}^{K_i^j} = \mathcal{F}(LLM(\cdot), p_f(f_i^j)), \qquad (6)
$$

397 where  $p_f$  is the prompt, which includes: (1) A clear task description. (2) Several instances. (3) The task containing the input sentence. The model is expected to output its extracted factors.

**401** After extracting factors, we then perform fact **402** correction, targeting only the extracted factors for **403** modification. This process can be represented as,

404 
$$
\hat{f}_i^j = \mathcal{R}(LLM(\cdot), p_r(f_i^j, \{fa_i^{j,k}\}_{k=1}^{K_i^j}, f_h)
$$
 (7)

405 where  $p_r$  is the prompt, which includes: (1) A clear task description. (2) Several instances. (3) The task containing the input target fact, the extracted fac-tors and the high-confidence reference facts. The

model is expected to output the modified target fact, **409** noting that the model allows for returning "NoEr- **410** ror" to make no modifications to the input. **411**

<span id="page-5-2"></span><span id="page-5-1"></span>Step 3: Fact Confidence Re-Estimation Finally, **412** the modified facts undergo the confidence estima- **413** tion process again to obtain new confidence scores: **414**

$$
\hat{conf}_i^j = \mathcal{C}(LLM(\cdot), p_c(\hat{f}_i^j, \mathbf{x}_i, \mathbf{y}_i)), \quad (8)
$$

where  $\hat{conf}_i^j$  represents the confidence score of the  $416$ modified fact  $\hat{f}_i^j$  $\hat{i}$ . Finally, if  $\hat{conf}_i^j > \hat{conf}_i^j$ , the 417 modification is deemed successful and is accepted. **418** Otherwise, ConFact will repeat the process of fac- **419** tor extraction, fact correction, and confidence re- **420** estimation. This iterative process continues until **421** either a satisfactory confidence score is achieved or **422** a predetermined maximum number of iterations N **423** is reached, where the model return "NoError" and **424** make no modifications to the input. **425** 

### **5 Experiment** 426

#### **5.1 Experiment Setup** 427

This section outlines the experimental setups, in- **428** cluding the datasets, models, and evaluation. **429**

Datasets We employ two datasets: (1) Long- **430** Fact [\(Wei et al.,](#page-9-7) [2024\)](#page-9-7): A dataset consisting of 431 prompts designed to assess a model's factuality **432** in long-form responses created by GPT-4. (2) **433** ASQA [\(Stelmakh et al.,](#page-9-8) [2022\)](#page-9-8): A dataset designed **434** for long-form question answering that uniquely **435** centers on ambiguous factoid questions. **436**

 Models We use five models from different fam- ilies and scales to validate our method, including: (1) Llama [\(Touvron et al.,](#page-9-9) [2023\)](#page-9-9): include Llama- [7](#page-8-7)b-chat and Llama-13b-chat. (2) Vicuna [\(Chiang](#page-8-7) [et al.,](#page-8-7) [2023\)](#page-8-7): include Vicuna-7b and Vicuna-13b. (3) GPT [\(Brown et al.,](#page-8-0) [2020\)](#page-8-0): GPT-3.5-turbo.

 Correctness and Relevance Evaluation For cor- rectness and relevance evaluation, we use the Search-Augmented Factuality Evaluator (SAFE), which is a pipeline proposed by [\(Wei et al.,](#page-9-7) [2024\)](#page-9-7) that employs LLMs as agents to automatically eval- uate the factuality of long-form responses. It uti- lizes a multi-step reasoning process that includes [s](#page-8-8)ending search queries to Google Search [\(Hillis](#page-8-8) [et al.,](#page-8-8) [2012\)](#page-8-8) to verify the information provided. For the fact correction evaluation, we use GPT-4 for zero-shot pair-wise evaluation (see prompts in Appendix [C\)](#page-10-0).

 Evaluation Metrics For calibration evaluation, [w](#page-8-5)e use Expected Calibration Error (ECE) [\(Guo](#page-8-5) [et al.,](#page-8-5) [2017a;](#page-8-5) [Naeini et al.,](#page-9-10) [2015\)](#page-9-10) at the response- level, and our F-ECE at the fact-level as introduced in section [3.2.](#page-3-2) For self-correction evaluation, the evaluation metrics are twofold. Firstly, we use Ac- curacy, Precision, and Recall [\(Powers,](#page-9-11) [2020\)](#page-9-11) to evaluate error detection. Then, we use improve- ment ratio, same ratio, and regression ratio to eval-uate self-correction.

#### **465** 5.2 Results for Fact-Level Calibration

 This section provides detailed implementation and comprehensive experiment results of our fact-level calibration framework. As introduced in sec-tion [3.3,](#page-3-3) we have three key observations.

<span id="page-6-0"></span>Table 1: Comparison of response-level and our factlevel calibration performance of five base models in terms of (F-)ECE under ASQA and LongFact datasets.

<b>Base Model</b>	Method	ASQA	LongFact
Llama-2-7b	Fact	0.261	0.211
	Response	0.251	0.141
Llama-2-13 $b$	Fact	0.240	0.156
	Response	0.261	0.131
Vicuna-7h	Fact	0.337	0.151
	Response	0.352	0.137
Vicuna-13 <sub>b</sub>	Fact	0.254	0.113
	Response	0.269	0.109
GPT-3.5-turbo	Fact	0.179	0.086
	Response	0.185	0.094

Calibration Comparison for Observation 1 For **470** Observation 1, we compare our fact-level and **471** response-level calibration in accordance with the **472** protocol in [\(Guo et al.,](#page-8-5) [2017a\)](#page-8-5). We illustrate relia- **473** bility histograms and compute the summary statis- **474** tics of ECE and our F-ECE to evaluate calibration. **475** The procedures are implemented as follows: For **476** fact-level, we evaluate confidence, correctness, and **477** relevance as described in section [3.2.](#page-2-1) For response- **478** level, we use a verbalization-based method follow- **479** ing the procedure in [\(Huang et al.,](#page-8-4) [2024\)](#page-8-4), where  $480$ the model is prompted to provide a single confi- **481** dence score for the whole response. For a detailed **482** prompt template, please refer to Appendix [C.](#page-10-0) For **483** the reliability histogram, we divided the model's **484** predictions into ten bins based on the confidence **485** score and calculated the average accuracy for each **486** bin. From the perspective of the histogram, an opti- **487** mally calibrated model should have its bar graph in **488** a diagonal shape to achieve the smallest gap area. **489** The results are depicted in fig. [3](#page-3-1) and table [1.](#page-6-0) 490

Across-Responses Confidence Distribution for **491** Observation 2 For Observation 2, we examine **492** how our fact-level calibration can mitigate the **493** over-confidence issue by analyzing the distribution **494** of confidence scores. The procedures are imple- **495** mented as follows: For the response-level, we use **496** a verbalization-based method to obtain a score for **497** each response and visualize its distribution across **498** the entire dataset using violin plots. For the fact- **499** level, since the confidence for a single response is **500** represented as a vector rather than a scalar, we com- **501** pute three different statistical measures: the mean, **502** maximum, and minimum of the vector. We then 503 visualize these measures as three separate violin **504** plots. The results are depicted in fig. [7.](#page-7-0) **505**

Within-Responses Confidence Distribution for **506 Observation 3** For Observation 3, we investigate 507 the variance in fact-level confidence within indi- **508** vidual responses. The procedures are implemented **509** as follows: For each response, we obtain its confi- **510** dence vector and visualize its distribution using box **511** plots. Due to space limitations, we have visualized **512** 10 responses for each model in each dataset in fig. [8,](#page-7-1) **513** whereas this number is 50 in fig. [5.](#page-4-1) The red bar 514 is the confidence score of the whole response at **515** response-level. **516**

#### 5.3 Results for Self-Correction **517**

Error Detection table [2](#page-7-2) presents the error detec- **518** tion results of our proposed method based on five **519**

<span id="page-7-0"></span>

Figure 7: Comparison of confidence distribution across different responses between fact-level and response-level. The purple are our fact-level distribution under different statistical metrics, the gray is the response-level distribution.

<span id="page-7-1"></span>

Figure 8: Confidence distribution within responses at the fact level, the red bar is the response-level score.

 different base models. It can be seen that, in terms of Accuracy and Precision, larger models perform better than smaller models, i.e., GPT > 13b > 7b. However, all models somewhat fall short in Recall, indicating that many erroneous facts are not being detected. This suggests that all models exhibit a certain degree of overconfidence, often considering incorrect answers to be correct.

 Error Correction table [3](#page-7-3) presents the error cor- rection results of our proposed method based on five different base models. It can be seen that, among the three outcomes "improve," "same," and "regress," our method achieves the highest propor- tion of "improve" for all models except LLaMA. This indicates that our method effectively enables the models to self-correct and achieve better gener-ation results.

#### **<sup>537</sup>** 6 Conclusion

 This paper introduces a novel fact-level calibration framework to address hallucination issues in long- form responses generated by LLMs. Traditional single-estimate confidence methods are inadequate for complex outputs with multiple facts. By eval-

<span id="page-7-2"></span>

<b>Base Model</b>		Accuracy $(\%)$ Precision $(\%)$ Recall $(\%)$	
GPT-3.5-turbo	83.29	87.89	13.71
Vicuna-7b	60.06	99.90	0.15
Vicuna-13 <sub>b</sub>	74.81	77.68	8.46
Llama-2- $7b$	64.26	67.86	13.35
Llama-2- $13b$	70.45	77.45	30.62

<span id="page-7-3"></span>Table 3: GPT-4 evaluation of the self-correction.

uating each fact's correctness and relevance indi- **543** vidually, both externally and internally, our frame- **544** work enables fine-grained confidence assessments. **545** It sets a higher standard than response-level ap- **546** proaches, mitigates over-confidence, and reveals **547** significant confidence variance among facts within **548** responses. Leveraging high-confidence facts for in- **549** context learning effectively mitigates hallucination, **550** as validated across multiple datasets and models. **551**

#### **<sup>552</sup>** 7 Limitations and Broader Impacts

 In this work, we propose a fact-level calibration framework and, based on this framework, intro- duce a confidence-guided fact-level self-correction method. However, for this self-correction method to be effective, the model itself must possess a cer- tain level of calibration ability. In our paper, we discuss how our calibration framework can allevi- ate over-confidence. In future work, we will further explore ways to enhance calibration ability within the calibration framework, paving the way for more effective confidence-guided self-correction.

#### **<sup>749</sup>** A Datasets

 LongFact [\(Wei et al.,](#page-9-7) [2024\)](#page-9-7): A dataset consist- ing of prompts designed to assess a model's fac- tuality in long-form responses created by GPT-4. This dataset includes a diverse range of topics and ensures that the prompts require detailed and nu- anced answers, making it a robust benchmark for evaluating the factual accuracy of language models in generating extended text. The dataset is partic- ularly valuable for testing the capabilities of mod- els in maintaining factual consistency over longer passages, which is crucial for applications such as content creation, summarization, and complex question answering.

 ASQA [\(Stelmakh et al.,](#page-9-8) [2022\)](#page-9-8): A dataset designed for long-form question answering that uniquely centers on ambiguous factoid questions. ASQA provides a challenging testbed for models as it includes questions that can have multiple valid answers depending on the interpretation of the am- biguity. This dataset emphasizes the need for mod- els to not only retrieve accurate information but also to handle the inherent uncertainty and provide comprehensive responses. ASQA is instrumental in pushing the boundaries of model performance in scenarios where clarity and precision are essential, such as in education and interactive AI systems.

#### **<sup>776</sup>** B Models

 [L](#page-9-9)lama-7b-chat & Llama-13b-chat [\(Touvron](#page-9-9) [et al.,](#page-9-9) [2023\)](#page-9-9): These models are part of the LLaMA family, known for their strong performance in various natural language processing tasks. The "chat" versions are particularly fine-tuned for con- versational contexts, making them suitable for gen- erating coherent and contextually appropriate re- sponses in dialogue settings. LLaMA models are designed to balance performance and computa- tional efficiency, making it a popular choice for research and application in interactive AI systems.

 Vicuna-7b and Vicuna-13b [\(Chiang et al.,](#page-8-7) [2023\)](#page-8-7) Vicuna is an open-source chatbot trained by fine-tuning LLaMA on user-shared conversations collected from ShareGPT. Preliminary evaluation using GPT-4 as a judge shows Vicuna-13B achieves more than 90% quality of ChatGPT and Bard while outperforming other models like LLaMA and Stan- ford Alpaca [\(Li et al.,](#page-9-12) [2023b;](#page-9-12) [Dubois et al.,](#page-8-9) [2024,](#page-8-9) [2023\)](#page-8-10) in more than 90% of cases.

GPT-3.5-turbo [\(Brown et al.,](#page-8-0) [2020\)](#page-8-0) This model **797** is part of OpenAI's well-known GPT series. GPT- **798** 3.5-turbo is an enhanced version of GPT-3, offer- **799** ing improved performance and efficiency. It is **800** designed to handle a wide range of language tasks, **801** from text generation to comprehension and trans- **802** lation. The "turbo" variant is optimized for faster **803** inference and lower latency, making it ideal for **804** real-time applications where quick response times **805** are crucial. GPT-3.5-turbo is widely used in both **806** research and industry due to its versatility and high- **807** quality output. **808** 

#### <span id="page-10-0"></span>C Prompts **<sup>809</sup>**

#### C.1 Prompt for Fact-Level Confidence **810** Estimation 811

The specific prompts used for fact-level confidence **812** estimation are detailed below.

Instructions: 1. The following STATEMENT has been extracted from the broader context of the given RESPONSE to the given QUESTION. 2. Indicate how confident you are in the accuracy of the STATEMENT when answering the QUESTION, based on your knowledge. 3. The confidence evaluation should be a value between 0 and 1 (with two decimal places retained), based on the following scoring criterion: {Criterion} 4. Your task is to do this for the STATEMENT, RESPONSE and QUESTION under "Your Task". Some examples have been provided for you to learn how to do this task.

{Some Examples}

Your Task: QUESTION: {Question} RESPONSE: {Response} STATEMENT: {Statement}

Table 4: Prompt for fact-level confidence estimation {Criterion}, {Question}, {Response} and {Statement} are placeholders.

**813**

#### C.2 Prompt for Response-Level Confidence **814** Estimation 815

The specific prompts used for response-level confi- **816** dence estimation are detailed below. **817**

Instructions: 1. The following RESPONSE is the answer to the given QUESTION. 2. Indicate how confident you are in the accuracy of the RESPONSE when answering the QUESTION, based on your knowledge. 3. The confidence evaluation should be a value between 0 and 1 (with two decimal places retained), based on the following scoring criterion: {Criterion} 4. Your task is to do this for the RESPONSE and QUESTION under "Your Task". Some examples have been provided for you to learn how to do this task. {Some Examples} Your Task:

QUESTION: {Question}

# RESPONSE:

{Response}

Table 5: Prompt for response-level confidence estimation {Criterion}, {Question}, {Response} and {Statement} are placeholders.

#### 818 **C.3 Prompt for Factor Extraction**

**819** The specific prompts used for factor extraction are detailed below.

> Instructions: You are to read a sentence and identify the key factors within it.

> The task involves pinpointing the essential elements or aspects that significantly influence or characterize the situation, event, or subject described.

> Return the identified key factors using the format <[factor1, factor2, ...]>

> Some examples have been provided for you to learn how to do this task.

{Some Examples}

Your Task: SENTENCE: {Sentence}

Table 6: Prompt for factor extraction {Sentence} is placeholders.

### **821** C.4 Prompt for Fact Correction

**822** The specific prompts used for fact correction are **823** detailed below.

#### **824** C.5 GPT-4 Judgments for Self-Correction

**825** For the self-correction, we utilize GPT-4 for zero-**826** shot pair-wise evaluation. We use gpt-4-0314 for

Instructions: You have been provided with a sentence and some reference knowledge. The sentence has been analyzed, and its factors have been identified. However, it is acknowledged that there may be errors or inaccuracies in the identified factors. Your task is to first review the identified factors and check for any errors or inaccuracies. If there are no errors, simply return "NoError" to indicate that no corrections are needed. If errors are present, proceed to make the necessary corrections. Ensure that the corrections are limited to the existing factors without adding new content. Use the format <old factor -> new factor> for each correction.

{Some Examples}

Your Task: SENTENCE: {Sentence}

FACTORS: {Factor}

REFERENCE: {Reference}

Table 7: Prompt for fact correction {Sentence}, {Factor} and {Reference} are placeholders.

all our experiments. The specific prompts used for **827** GPT-4 evaluation are detailed below. **828**

You will be provided with a QUESTION, its RESPONSE, and all facts extracted from the RESPONSE under the heading "ALL FACTS". You will also be provided with a specific fact under the heading "TARGET FACT 1", which is included in ALL FACTS. Additionally, you will be given a modified version of this target fact under the heading "TARGET FACT 2".

Based on your knowledge, evaluate whether the modification of the target fact is an improvement, the same, or a regression.

An improvement implies:

- 1. More accurate information.
- 2. Greater relevance to the question.
- 3. Minimal overlap with other facts in ALL FACTS.

A regression implies: 1. Introduction of erroneous or inaccurate information. 2. Lower relevance to the question. 3. Repetition or introduction of information that is already provided with other facts in ALL FACTS.

QUESTION: {Question}

RESPONSE: {Response}

ALL FACTS: {All Facts}

TARGET FACT 1: {Original Fact}

TARGET FACT 2: {New Fact}

First, provide a one-sentence comparison of the two facts and explain whether you think the modification is an improvement, the same, or a regression. Second, on a new line, the state only "IMPROVED", "SAME", or "REGRESSED" to indicate the effectiveness of the modification. Your response should use the following format: <one-sentence comparison and explanation> REVISION: <"IMPROVED", "SAME", or "REGRESSED">

Table 8: Prompt for GPT-4 evaluation for the selfcorrection {Question}, {Response}, {All Facts}, {All Facts}, {Original Facts} and {New Fact} are placeholders.
