

QC-BENCH: WHAT DO LANGUAGE MODELS KNOW ABOUT QUANTUM COMPUTING?

005 **Anonymous authors**

006 Paper under double-blind review

ABSTRACT

011 Language models have become practical tools for quantum computing education
 012 and research, from summarizing technical papers to explaining theoretical concepts.
 013 While existing benchmarks evaluate quantum code generation and circuit design,
 014 their understanding of quantum computing concepts has not been systematically
 015 measured. QC-Bench addresses this gap with over 6,000 expert-level questions
 016 on quantum algorithms, error correction, and security protocols. Evaluating 31
 017 models from OpenAI, Anthropic, Google, and Meta reveals strong performance on
 018 established theory but systematic failures on advanced topics like quantum security
 019 and recent attack vectors. Human participants scored between 23% and 86%,
 020 with experts averaging 74% and all participants averaging 57%. Top-performing
 021 models exceeded the expert average, with Claude Sonnet 4 and GPT-5 reaching
 022 88% overall, yet dropping to 76% on security questions. Additional evaluation
 023 across question formats and languages reveals variation in model performance,
 024 demonstrating that QC-Bench provides a necessary framework for measuring
 025 language model reliability in quantum computing contexts.

1 INTRODUCTION

029 Quantum computing has progressed significantly from theoretical research to experimental implemen-
 030 tations with practical applications. Current quantum systems have rapidly evolved through successive
 031 technological breakthroughs from operating with just a few qubits to recently surpassing the 1000-
 032 qubit barrier AbuGhanem (2025), enabling exploration of quantum algorithms and protocols that were
 033 previously confined to theoretical analysis. This technical advancement drives progress in quantum
 034 simulation King et al. (2025); Halimeh et al. (2025); Puig et al. (2025), optimization problems Quinton
 035 et al. (2025); Phillipson (2024), and cryptographic applications Sahu & Mazumdar (2024);
 036 Ralegankar et al. (2021); Kalaivani et al. (2021). Beyond traditional quantum applications such as
 037 quantum simulation and cryptography, recent research explores its potential in finance Innan et al.
 038 (2024); Grossi et al. (2022), healthcare Ur Rasool et al. (2023); Flöther (2023), computer vision Li
 039 et al. (2020); Afane et al. (2025); ALRikabi et al. (2022), and wireless communication Narottama &
 040 Shin (2021); Narottama et al. (2023), among other promising real-world applications.

041 In parallel, Large Language Models (LLMs) have become sophisticated tools that address com-
 042 plex challenges across many disciplines. These AI systems now approach or exceed human expert
 043 performance in areas such as cybersecurity Tihanyi et al. (2024); Afane et al. (2024), medical diag-
 044 nosis Subedi (2025), and legal reasoning Guha et al. (2023); Kant et al. (2025). As these two fields
 045 continue to evolve, their intersection becomes increasingly important for scientific communication,
 046 education, and research productivity. Despite significant advances in both domains, we face a critical
 047 knowledge gap in evaluating LLMs' understanding of specialized quantum concepts. While extensive
 048 benchmarking exists across numerous related domains, including mathematics Gao et al. (2024);
 049 Fang et al. (2024), physics Chung et al. (2025), and computer science Song et al. (2024), no stan-
 050 dardized frameworks comprehensively assess quantum computing knowledge in these models. This
 051 absence is particularly concerning given the field's counterintuitive principles, and rapidly evolving
 052 terminology that challenge even domain experts. The complexity of quantum computing concepts,
 053 combined with their inherent mathematical abstraction, creates a particularly demanding test case for
 evaluating the depth of LLMs' specialized knowledge. Without reliable evaluation metrics, LLMs risk
 spreading plausible but incorrect quantum information to educational and research communities, as

054 hallucinations, reasoning errors, and factual inaccuracies have been widely documented in similarly
 055 complex and technically demanding specialized domains. Orgad et al. (2024); Perković et al. (2024).
 056

057 This creates an urgent need for robust quantum computing benchmarks as researchers, students,
 058 and industry professionals increasingly rely on these models for information and assistance with
 059 quantum tasks. The growing adoption of LLMs across academic institutions and quantum technology
 060 companies further amplifies the importance of ensuring these systems provide accurate information
 061 on this emerging field. To address these challenges, we present the following key contributions:

- 062 • We assemble **6,237 questions**: 5,400 multiple-choice questions comprising QC1000 (1,000
 063 entirely human-authored from peer-reviewed literature, with QC500 translated into Spanish
 064 and French) and 4,400 human-validated questions filtered from 8,686 candidates, plus 837
 065 format variants (416 true/false, 421 open-ended) for evaluating model performance across
 066 question formats.
- 067 • We conduct extensive evaluation across **31 models** from leading AI research organizations
 068 including OpenAI, Anthropic, Google, Meta, IBM, Microsoft, and DeepSeek, among others.
 069 We compare their performance against 43 quantum computing experts and practitioners to
 070 establish human baselines and assess how LLMs perform relative to human capabilities.
- 071 • We analyze model performance across different question formats and via Spanish and French
 072 translations of QC500, revealing significant accuracy declines in the translated sets and
 073 consistent sensitivity to question type, with larger drops in Spanish than in French.
- 074 • We explore the potential of our dataset for fine-tuning by using a subset of 4,000 questions
 075 to enhance the quantum knowledge of five smaller models, demonstrating performance
 076 improvements and establishing the benchmark’s value beyond evaluation.

078 2 RELATED WORK

080 Despite significant advancements in both quantum computing and LLMs, their intersection remains
 081 surprisingly underexplored. Recent research has begun addressing this gap from different angles.
 082 Kashani Kashani (2024) introduced QuantumLLMInstruct (QLMMI), a dataset of over 500,000
 083 instruction-problem pairs covering quantum cryptography, spin chain models, and Trotter-Suzuki
 084 decompositions. However, QLMMI’s primary purpose is to enable instruction fine-tuning rather than
 085 comprehensive evaluation of quantum knowledge. While extensive in size, QLMMI relies entirely on
 086 synthetically generated content through a four-stage LLM pipeline. In contrast, QC-Bench offers
 087 1,200 human-authored evaluation questions extracted directly from research literature published
 088 over four decades, prioritizing authentic scientific content over synthetic generation. Wang et al.
 089 Wang et al. (2024) introduced GroverGPT, an approach to simulating quantum algorithms using
 090 LLMs. Their 8-billion-parameter model is fine-tuned to approximate Grover’s quantum search
 091 algorithm without explicitly representing quantum states. While GroverGPT demonstrates impressive
 092 capabilities in predicting specific quantum circuit outputs, it focuses exclusively on a single quantum
 093 algorithm rather than evaluating comprehensive knowledge across the quantum computing domain.

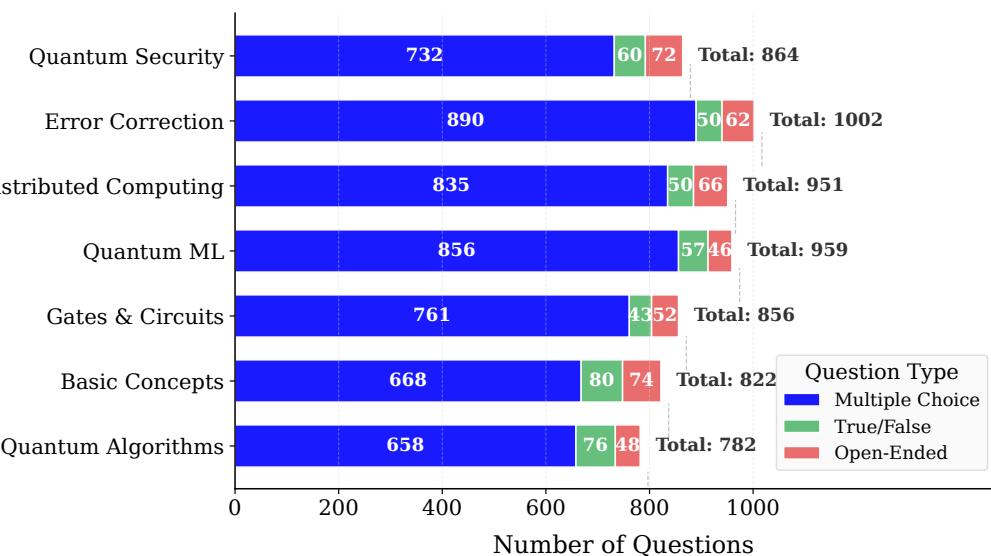

094 Complementary efforts have emerged focusing on quantum code generation and circuit implemen-
 095 tation capabilities. Vishwakarma et al. Vishwakarma et al. (2024) developed Qiskit HumanEval, a
 096 hand-curated benchmark of over 100 tasks designed to evaluate LLM performance in generating
 097 executable quantum code using the Qiskit SDK, complete with canonical solutions and com-
 098 prehensive test cases. Guo et al. Guo et al. (2025) introduced QuanBench, which evaluates quantum
 099 code generation across 44 programming tasks using both functional correctness (Pass@K) and
 100 quantum semantic equivalence (Process Fidelity) metrics, finding that current LLMs achieve below
 101 40% overall accuracy with frequent semantic errors including outdated API usage and incorrect
 102 algorithm logic. Yang et al. Yang et al. (2024) presented QCircuitNet, a large-scale hierarchical
 103 dataset for quantum algorithm design containing 120,290 data points with automatic syntax and
 104 semantic verification functions. At a lower abstraction level, Li et al. Li et al. (2023) developed
 105 QASMBench, a benchmark suite of low-level OpenQASM programs for evaluating NISQ devices and
 106 simulators. While these works provide valuable resources for assessing programming proficiency and
 107 implementation capabilities at various levels of quantum software development, they primarily target
 108 coding skills rather than evaluating deep conceptual understanding of quantum computing principles,
 109 algorithmic theory, or the ability to reason about quantum phenomena. QC-Bench addresses this by

108 evaluating theoretical knowledge and conceptual understanding across quantum computing topics,
 109 from foundational algorithmic principles to advanced security protocols and attack vectors.
 110

111 3 QC-BENCH DATASET

112
 113 We constructed the QC-Bench dataset to evaluate quantum computing knowledge in LLMs across
 114 a wide range of topics and difficulty levels. To ensure comprehensive coverage and relevance,
 115 our team reviewed over 200 peer-reviewed research papers, preprints, and academic resources.
 116 From these sources, questions were directly selected to reflect both foundational knowledge and
 117 current advancements in the field. The dataset comprises QC1000, containing 1000 questions
 118 manually extracted from quantum computing literature, with QC500 as a 500-question subset
 119 selected for multilingual evaluation. To address concerns about model memorization, none of these
 120 questions are reproduced verbatim from source materials; instead, we extracted core concepts and
 121 reformulated them into original questions. This approach ensures that performance reflects genuine
 122 understanding rather than memorization of published text. After refining and validating this content,
 123 the benchmarks were finalized. The QC500 subset was translated into Spanish and French to evaluate
 124 LLM performance in languages other than English.

125 To expand our benchmark, Gemini 2.0 Flash, Gemini 1.5 Pro, GPT-4.0, and Claude 3.7 Sonnet
 126 were employed to extract additional relevant questions from the selected papers. Different prompt
 127 engineering techniques were tested to optimize question generation quality. While zero-shot prompting
 128 produced acceptable results, few-shot prompting with five carefully selected examples from the
 129 existing subsets significantly improved the relevance and technical accuracy of generated questions.
 130 This approach generated 8,686 candidate questions, subsequently filtered to remove low-quality or
 131 redundant items. The final selection included an additional 4,400 high-quality questions, bringing
 132 the total benchmark size to 5,400 multiple-choice questions. To evaluate model performance across
 133 different question formats, the benchmark was supplemented with 416 true/false questions and 421
 134 open-ended questions. Figure 1 illustrates the distribution of these question types across different
 135 topics. **Given the interconnected nature of quantum computing, some concepts naturally appear**
 136 **across multiple categories; for example, noise characterization relates to both error correction and**
 137 **hardware-level circuit design.** The multiple-choice format enables precise evaluation of factual
 138 recall and conceptual understanding, while true/false questions assess binary comprehension, and
 139 open-ended questions evaluate explanatory capabilities.

158 Figure 1: Breakdown of benchmark question topics and their internal composition by question type.
 159 Each horizontal bar shows the total number of questions per topic. We intentionally included a larger
 160 share of multiple choice items to enable standardized automated evaluation, whereas true/false items
 161 offer limited challenge and open-ended questions require manual scoring.

162 4 EXPERIMENTS

164 We evaluated 31 LLMs using a consistent benchmarking pipeline. Closed-source models, including
 165 GPT-5, GPT-4o (standard, mini), Claude (Sonnet 4, Sonnet 3.7, Haiku 3.5), and Gemini (1.5 Pro,
 166 2.0 Flash), were accessed through their official APIs in Google Colab environments. Open-access
 167 models such as LLaMA3 (1B, 8B, 70B), LLaMA2 (13B), Phi (2.7B, 3.8B, 14.7B), Mistral (7B,
 168 24B), Qwen1.5 (2.7B, MoE-A2.7B), Zephyr, DeepSeek, Gemma, Granite, and GPT-J were deployed
 169 using Hugging Face’s Transformers library on a cluster equipped with two Tesla V100 GPUs (32GB
 170 each) using FP16 inference. For several larger models, including llama-3 (70b, 70b-versatile), and
 171 Gemini-9B, we used Groq’s API instead of Hugging Face’s Transformers library for a faster and
 172 more efficient evaluation. All models were configured with a temperature setting of 1 to balance
 173 deterministic responses with reasonable diversity in answer generation.

174 For experiment preparation, all benchmark questions were structured in JSON format for efficient
 175 processing and consistent evaluation across different model architectures. We developed standardized
 176 prompting templates for each question type to ensure fair comparison between models. This data
 177 preparation approach facilitated automated evaluation pipelines and ensured comparable results
 178 despite the diversity of model implementations and access methods. The benchmark includes
 179 multiple-choice, true/false, and open-ended formats, with multilingual versions available for a subset
 180 of questions. Key findings from these experiments are presented in the following subsections, with
 181 complete results and detailed analyses available in the appendix.

208 Table 1: Evaluated language models with provider, size, access method, and accuracy on QC500,
 209 QC1000, and QC5400. Rows shaded in green mark the highest performing models overall, and rows
 210 shaded in light blue mark the best performing open-source models.

212 4.1 COMPREHENSIVE MODEL EVALUATION ON CORE BENCHMARK AND ACROSS TOPICS

214 Table 1 details the characteristics of each evaluated model and summarizes performance across the
 215 three benchmark subsets. Results from these experiments demonstrate that increasing dataset size
 216 from 500 to 5,400 questions does not substantially impact relative model performance.

Table 2: Model accuracy on selected quantum topics. Accuracy above 90% are shaded green and those below 50% are shaded red.

Models performing well on QC500 and QC1000 maintained comparable performance levels on larger benchmarks, suggesting that a carefully selected sample of a few hundred questions provides sufficient evaluation of quantum computing knowledge. Among the evaluated models, Claude 4 Sonnet achieved the highest overall performance, closely followed by GPT-5, GPT-4o, and Claude Sonnet 3.7. Notably, among open-source models, Phi-4-reasoning-plus, IBM Granite-3.3-8b-instruct, and Llama-3.1-8B-Instruct demonstrated reasonable performance on quantum computing tasks despite their smaller parameter counts. While these models still trail behind the larger proprietary systems, their relative competence suggests they could serve as practical starting points for domain-specific fine-tuning where computational resources are limited.

Table 2 shows a clear pattern: models handle basic concepts but decline sharply on advanced material, with the largest drop on quantum algorithms and security. Security questions were especially difficult, including recent work on phase mismatch attacks, crosstalk exploitation, QubitHammer, and quantum backdoors. These gaps highlight the challenge of fast moving areas that demand specialized knowledge, and the examples that follow illustrate the kinds of questions where even top models failed.

- What specific attack technique can manipulate the error rates of specific quantum gates ?
- What specific vulnerability does a quantum reorder attack exploit?
- What makes dynamical decoupling ineffective against QubitHammer attacks ?

This performance gap between foundational and advanced topics is particularly revealing. The disparity suggests that models have absorbed well-documented principles from extensive training data but struggle with recent developments where literature is sparser and terminology less standardized. The consistency of this pattern across model families, regardless of size or provider, indicates that the

challenge lies in the nature of the material rather than individual model limitations. Notably, even the expanded evaluation with agentic and deep research modes (Section 4.5) showed only marginal improvements on these advanced topics, confirming that web access alone cannot compensate for gaps in specialized reasoning. This finding has practical implications: users relying on LLMs for quantum computing assistance should exercise particular caution in rapidly evolving subfields where model knowledge may lag behind current research.

4.2 HUMAN PERFORMANCE BASELINE STUDY

To establish a human baseline for comparison with language model performance, we conducted a survey study with quantum computing researchers and practitioners. We carefully selected 30 questions from QC-Bench spanning different topic areas and complexity levels to assess human expertise across the quantum computing domain. The survey included questions from all seven categories. Participants were recruited from academic institutions and quantum computing research groups. Each respondent provided background information including their highest education level, years of experience in quantum computing, and age group. Further details on each participant's background and individual score are provided in the appendix, offering context for the distribution shown here. The sample questions below illustrate the style and difficulty of the survey items used in this comparison.

Sample Survey Questions

- Why is Shor’s algorithm considered a threat to modern cryptographic security?
- How does quantum transpilation optimize quantum circuits for real hardware?
- Which quantum algorithm is specifically designed to process structured graph data?

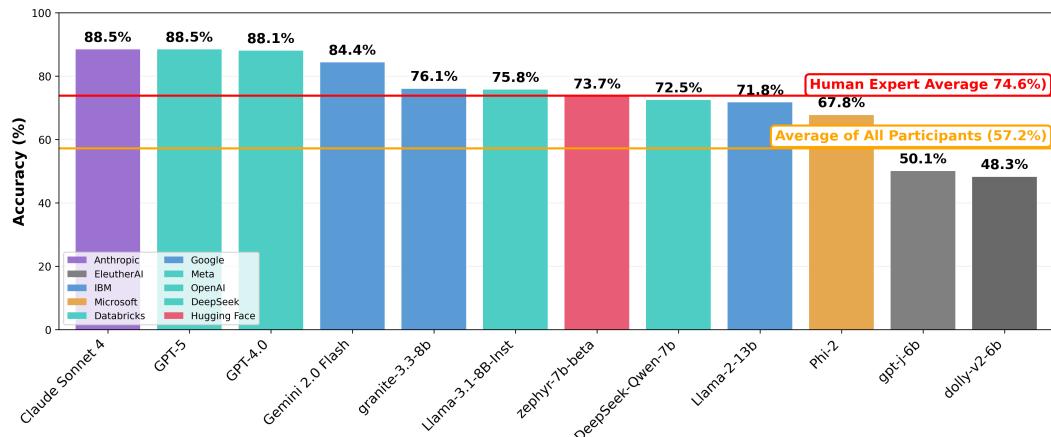

Figure 2: Performance comparison of selected LLMs across different capability tiers on the QC500 benchmark against human baselines. The visualization includes 12 representative models ranging from top performers to those scoring below novice human levels. Bars are colored by model provider.

Figure 2 presents a representative sample of LLM performance on the QC500 benchmark, showcasing models across the full performance spectrum. The majority of models shown exceed the all-participants average of 57.2%, while several surpass the expert average of 74.6%. The visualization highlights the dramatic performance range in quantum computing capabilities, from leading models like Claude 4 Sonnet (88.55%) and GPT-5 (88.07%) to models performing well below novice human levels, such as gpt-j-6b (50.14%) and dolly-v1-6b (48.29%). This selection demonstrates that quantum computing proficiency varies significantly across model families, sizes, and providers.

324 4.3 PERFORMANCE ACROSS DIFFERENT QUESTION FORMATS
325326 Our evaluation extended beyond multiple-choice questions to assess model capabilities in diverse
327 testing scenarios. For true/false questions, we modified the standard prompts to request binary
328 verification of quantum computing statements. In open-ended questions we evaluated models' ability
329 to generate explanations independently without options. Open-ended responses were graded based
330 on factual correctness and conceptual completeness, with multiple-choice questions serving as the
331 primary evaluation method while open-ended questions function as a supplementary diagnostic
332 tool. Most models maintained strong performance on the true/false questions while showing clear
333 degradation on open-ended assessments. Accuracy on the true/false set was tightly clustered, with
334 smaller models often matching the large models once the task was reduced to a simple binary choice.335 The limited number of options in the true/false evaluation leaves less room to distinguish stronger
336 reasoning ability, so the gap between the very top systems and the weakest models nearly disappears
337 in this format. By contrast, multiple-choice questions with four options revealed a more visible
338 separation among high-end models, highlighting that true/false items are not an effective way to
339 validate deeper research questions. Open-ended questions told a different story. GPT-5 not only
340 produced the highest scoring answers when evaluated for correctness but also consistently provided
341 richer, more contextually grounded explanations than its peers, and those detailed responses were
342 closely aligned with the correct conclusions in most cases. This pattern underscores that open-ended
343 evaluation exposes real differences in reasoning quality that are obscured when models face only
344 binary decisions. Table 3 presents the complete results.345
346 4.4 FINE-TUNING POTENTIAL FOR QUANTUM KNOWLEDGE
347348 We explored QC-Bench's utility for enhancing quantum computing capabilities through targeted
349 fine-tuning. Using a subset of 4,400 questions for training and 1,000 questions as a test set, we
350 fine-tuned five smaller language models using LoRA (Low-Rank Adaptation).351 Our fine-tuning implementation used PyTorch with the Transformers library, applying LoRA with
352 rank=8 and alpha=16 targeting attention projection matrices. We used a learning rate of 1e-4 with
353 AdamW optimizer, batch size of 4 with gradient accumulation over 4 steps, and trained for a single
354 epoch with warmup steps to ensure stable adaptation without overfitting.355 Table 4 demonstrates the results across our selected models. Llama-3.1-8B-Instruct showed the
356 strongest adaptation with a 5% improvement, while Gemma 2B achieved a modest 3.7% gain.
357 Qwen1.5-MoE-A2.7B showed minimal improvement despite its Mixture-of-Experts architecture.
358 Surprisingly, Phi-4-mini-reasoning experienced a slight performance decline, and EleutherAI/gpt-j-6b
359 demonstrated a substantial 7% drop in accuracy. These mixed results highlight how model architecture
360 significantly influences fine-tuning outcomes, with instruction-tuned models generally showing better
361 adaptation to specialized quantum computing knowledge than their general-purpose counterparts.362
363
364

Model	T/F (%)	O-E (%)
GPT-5	93.27	89.07
Claude Sonnet 4	93.99	88.84
GPT-4o	93.75	86.22
Gemini 2.0 Flash	92.31	84.09

378 4.5 PERFORMANCE WITH AGENTIC AND DEEP RESEARCH MODES
379380 Given the limited improvements observed from fine-tuning and the practical constraints of adapting
381 larger models, we explored an alternative approach through agentic reasoning capabilities and deep
382 research modes. These capabilities enable models to perform multi-step reasoning, search external
383 sources, and synthesize information across multiple queries without requiring model adaptation or
384 training data. This paradigm augments models with tool use and extended reasoning processes rather
385 than modifying model weights to encode domain-specific knowledge. We evaluated frontier models
386 equipped with their respective advanced capabilities: Claude Sonnet 4.5 Research Mode, Claude
387 Sonnet 4.5 Extended Thinking, GPT-5.1 Deep Research, GPT-5.1 Agent Mode, and Gemini 3 Deep
388 Research. These modes allow models to break down complex questions, search for relevant informa-
389 tion, and synthesize answers through multi-step reasoning processes. We tested these capabilities on
390 the QC500 subset, which provides a balanced evaluation across all quantum computing topics in our
391 benchmark.
392

393 Model	394 Before (%)	395 After (%)	396 Improvement
394 Claude Sonnet 4.5 (Research Mode)	395 91.80	396 92.20	+0.40
394 Claude Sonnet 4.5 (Extended Thinking)	395 91.80	396 92.60	+0.80
394 GPT-5.1 (Deep Research)	395 91.40	396 92.80	+1.40
394 GPT-5.1 (Agent Mode)	395 91.40	396 91.20	-0.20
394 Gemini 3 (Deep Research)	395 87.40	396 89.20	+1.80

400 Table 5: Performance of frontier models with advanced reasoning capabilities on QC500. Average
401 improvement is 0.84 percentage points.
402403 Results in Table 5 show the performance of these advanced reasoning modes. GPT-5.1 with Deep
404 Research achieved the highest score at 92.80%, while both Claude Sonnet 4.5 variants performed
405 above 92%. Gemini 3 Deep Research showed the largest improvement, gaining 1.8 percentage points
406 to reach 89.20%. Notably, GPT-5.1 Agent Mode showed a slight decline of 0.2 percentage points
407 compared to the base model. The average improvement across all models was 0.84 percentage points,
408 demonstrating modest gains from these advanced capabilities.
409410 These results indicate that while agentic and deep research modes provide measurable benefits, the
411 improvements remain relatively modest on our benchmark. This suggests that the fundamental
412 challenge in quantum computing knowledge assessment lies in the breadth and depth of knowledge
413 encoded during pretraining rather than in reasoning capabilities alone. Questions in QC-Bench are
414 designed to test factual knowledge and conceptual understanding rather than multi-step reasoning,
415 which may explain why reasoning-augmented modes show limited advantage. However, advanced
416 reasoning modes offer key advantages: (1) they require no training data or computational resources for
417 model adaptation, (2) they can access current information beyond the model’s knowledge cutoff, and
418 (3) they can be applied to the largest and most capable models where fine-tuning is often impractical.
419420 4.6 MULTILINGUAL BENCHMARK PERFORMANCE
421422 To investigate how quantum computing knowledge transfers across languages, we evaluated all models
423 on Spanish and French translations of QC500. This experiment provides quantitative insights into
424 linguistic generalization of specialized technical knowledge. Figure 3 shows Spanish versus French
425 accuracy for selected models. While most models fall along a diagonal cluster indicating correlated
426 cross-lingual performance, the distribution reveals systematic language-dependent performance
427 gaps. Across our full benchmark set, models lose on average 11.2 percentage points in French
428 and 15.2 percentage points in Spanish relative to English baselines. This asymmetry is particularly
429 notable, as Spanish exhibits approximately 55 percent greater performance degradation than French.
430 Remarkably, only 34.5% of models maintain scores above 75% in Spanish, compared to 44.8% in
431 French and 69.0% in English. The most linguistically consistent models (Claude 4 Sonnet, GPT-5,
432 and Gemini 2.0 Flash) show standard deviations below 0.6 across languages, while the least consistent
433 (Phi-4-reasoning) exhibits a standard deviation of 31.2.
434

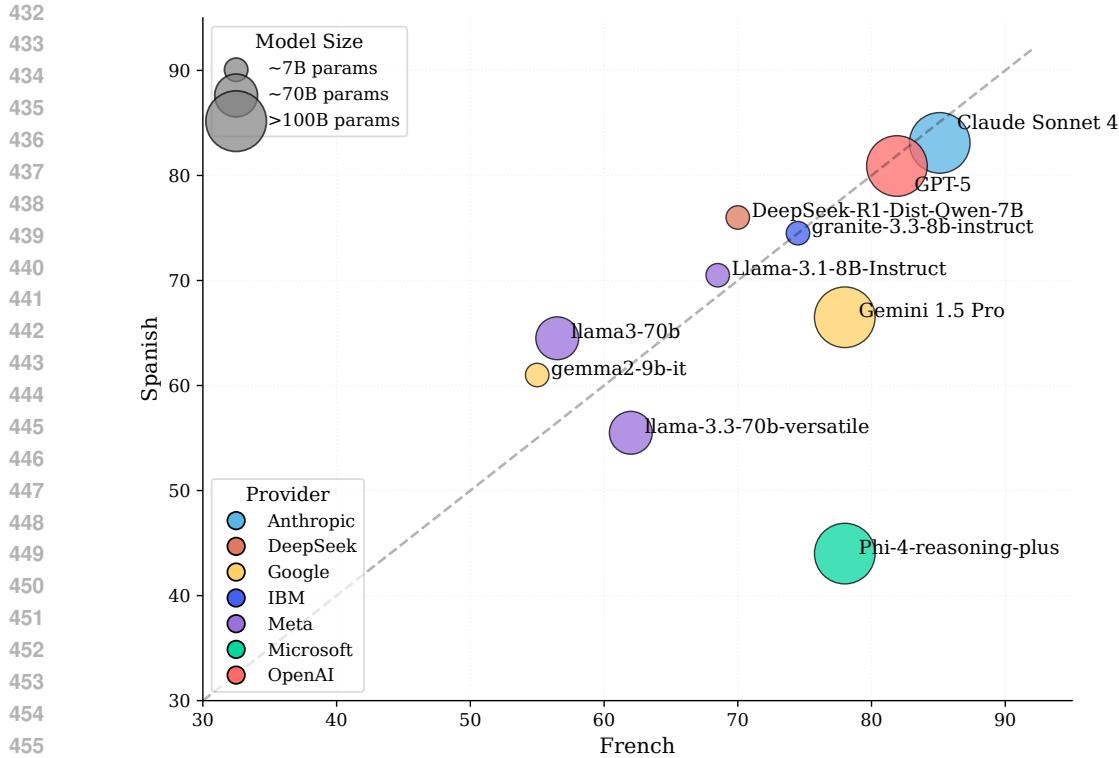

Figure 3: Bubble chart of Spanish (vertical) versus French (horizontal) accuracy on the QC500 benchmark. Each bubble’s area is proportional to the model’s parameter count; colors indicate providers. The diagonal dashed line marks equal performance across the two languages. Bubbles below the line signal larger accuracy loss in Spanish.

5 DISCUSSION

Our evaluation reveals a clear performance pattern across all tested models: strong results on foundational topics with significant decline on advanced domains. Top models achieve over 92% accuracy on basic quantum concepts but drop below 77% for quantum security questions. This performance drop is particularly evident in questions about emerging attack vectors like phase mismatch attacks and QubitHammer, where even the most advanced models failed to provide accurate responses consistently. Notably, leading LLMs outperform many practitioners and experts in our human survey, where performance ranged from 26.6% to 86% depending on education level and experience (detailed results in the appendix). In addition, the results highlight a widening gap between recent state-of-the-art LLMs and smaller models, a trend that persists even after fine-tuning. These high-capacity systems show clear advantages not only on complex multiple-choice tasks but especially on open-ended questions, where they deliver more accurate and detailed explanations. Smaller models, by contrast, plateau despite fine-tuning, indicating that model scale and training pipelines remain critical for strong performance on demanding quantum computing assessments.

Question format comparison shows GPT-5 maintaining 89.07% accuracy on open-ended quantum explanations while most competitors show degradation without multiple-choice options. This suggests many models rely on recognizing answer patterns rather than constructing explanations from fundamental understanding. Our multilingual testing reveals concerning disparities, with average performance dropping 11.2 percentage points in French and 15.2 points in Spanish. Fine-tuning results demonstrate significant variation in how models adapt to quantum knowledge. Llama-3.1-8B-Instruct improved by 5.3% through fine-tuning, while EleutherAI/gpt-j-6b declined by 7%, suggesting that instruction-tuned models more readily incorporate specialized quantum knowledge.

486 As quantum computing advances toward practical implementation, retrieval-augmented generation
 487 can complement fine-tuning, particularly since practical fine-tuning is mainly feasible for smaller
 488 models. While targeted fine-tuning can modestly improve accuracy for compact systems, it remains
 489 costly and inflexible for the larger architectures that already set the performance frontier. Retrieval-
 490 augmented generation, by contrast, allows those high-capacity LLMs to access curated domain
 491 sources and continuously updated technical literature, avoiding the need for repeated full retraining.
 492
 493

494 6 LIMITATIONS AND FUTURE WORK

495
 496 QC-Bench offers a comprehensive evaluation of quantum computing knowledge, with English as the primary language and a large QC500 subset already available in Spanish and French. A next step is to expand coverage beyond QC500 by translating a larger portion of the benchmark into Spanish and French, and by adding more languages to better reflect global practice. Additional work includes increasing the diversity of non-English source materials and assessing cross-lingual consistency to provide a more complete view of multilingual performance.
 500
 501
 502

503 Our evaluation relies primarily on accuracy as the central performance metric, which effectively captures models' factual knowledge but may not fully represent their conceptual understanding or reasoning capabilities. We chose accuracy for its interpretability, directness, and alignment with our goal of measuring factual correctness in quantum computing knowledge. Future research could explore alternative metrics such as calibration scores for confidence assessment, partial credit scoring for near-correct responses, or semantic similarity measures for evaluating open-ended explanations beyond binary correctness judgments.
 504
 505
 506
 507
 508

509 **510 Additionally, incorporating statistical frameworks such as error bars and confidence intervals would 511 enhance the interpretability of results, as discussed by Miller (2024). Given the extensive nature of 512 our evaluation across 31 models, multiple question formats, three languages, fine-tuning experiments, 513 and agentic evaluation modes, incorporating this level of statistical rigor was beyond the current 514 scope. We leave this as a direction for future work.**
 515
 516

517 7 CONCLUSION

518
 519 As Large Language Models (LLMs) are increasingly tasked with reading, explaining, and answering
 520 questions about quantum computing literature, rigorous domain evaluation is essential. QC-Bench
 521 provides a comprehensive assessment with 5,400 multiple-choice items plus 416 true/false and 421
 522 open-ended questions across seven core domains. Across 31 systems, we find a consistent pattern:
 523 strong results on foundational material but marked drops on advanced topics. Top systems clear 92%
 524 on basic concepts yet fall below 77% on security questions, including items on recent developments
 525 in quantum security. Format matters: many models score well on multiple choice but degrade on
 526 open-ended responses; GPT-5 maintains the strongest open-ended performance among evaluated
 527 systems (89.07%) and produces more detailed, context-grounded explanations. Relative to human
 528 baselines (23.3%–86.7%), eight models exceed the all-participants average of 74.6% and surpass the
 529 expert average of 80.0%. Multilingual testing shows asymmetry, with average accuracy declines of
 530 11.2 points in French and 16.2 in Spanish relative to English, indicating that quantum knowledge
 531 does not transfer uniformly across languages.

532 Methodologically, the results indicate a widening gap between state-of-the-art, high-capacity systems
 533 and smaller models, a difference that persists even after fine-tuning. Gains from fine-tuning are
 534 modest, typically only a few percentage points, and can sometimes reduce accuracy, making the
 535 computational cost difficult to justify for larger architectures. Evaluation of frontier models with
 536 agentic and deep research capabilities showed an average improvement of only 0.84 percentage
 537 points even with full internet access, suggesting that web search alone cannot compensate for gaps in
 538 specialized technical reasoning. Alternative approaches for enhancing performance on demanding
 539 technical domains remain an open research question. Quantum computing remains one of the most
 demanding areas for language models, and continued evaluation of LLM capabilities in this domain
 is essential for tracking progress and ensuring reliable performance as the field evolves.

1245 **A.1 QUESTION EXTRACTION AND GENERATION**
12461247 For the QC500 and QC1000 subsets, researchers systematically reviewed the selected quantum
1248 computing papers and identified key concepts, algorithms, and principles that capture both foun-
1249 dational and advanced material. Rather than copying sentences directly, each question was crafted
1250 by rephrasing important findings and definitions from the literature to create original items while
1251 preserving scientific accuracy. Draft questions underwent multiple rounds of verification for technical
1252 correctness and clarity to ensure they tested understanding rather than memorization of phrasing. In
1253 parallel, we leveraged language models in a controlled setting to suggest candidate questions from
1254 the same source papers, but every suggestion was filtered and rewritten by researchers to maintain
1255 consistency with the human-validated style and difficulty. This combined process produced a balanced
1256 set of high-quality questions that reflect authentic quantum computing research while supporting
1257 rigorous evaluation across diverse topics and difficulty levels. The question creation process involved
1258 developing multiple answer options for each extracted concept. Below we illustrate this process with
1259 an example:
12601261 **Example: Question Development Process**
12621263 **Initial concept from paper:** Quantum circuit synthesis involves decomposing unitary
1264 operations into implementable gate sequences.
12651266 **Generated question:** What is the primary purpose of quantum circuit synthesis?
12671268 **Initial answer options (6 generated):**1269 A. To convert a quantum circuit into a classical circuit by removing superposition
1270 properties
1271 B. To merge multiple unitary matrices into a single high-dimensional operator without
1272 gate decomposition
1273 C. To decompose a unitary matrix representing the circuit into a sequence of gates from
1274 the native gate set
1275 D. To encode classical information into qubit states without performing any gate-level
1276 modifications
1277 E. To simulate quantum circuits on classical computers using tensor networks
1278 F. To optimize quantum algorithms for specific hardware architectures
12791280 **Final selection (4 options):** Options E and F were eliminated as they describe related but
1281 distinct processes. The final question includes the correct answer (C) and three plausible
1282 distractors that test understanding of quantum circuit concepts.
12831284 **Quantum Circuit Synthesis**
12851286 **Question:** What is the primary purpose of quantum circuit synthesis?
12871288 A. To convert a quantum circuit into a classical circuit by removing superposition
1289 properties
1290 B. To merge multiple unitary matrices into a single high-dimensional operator without
1291 gate decomposition
1292 C. To decompose a unitary matrix representing the circuit into a sequence of gates from
1293 the native gate set
1294 D. To encode classical information into qubit states without performing any gate-level
1295 modifications1296 **Answer:** C

1296
1297

A.2 AUTOMATED QUESTION MINING FROM RESEARCH PAPERS

1298
1299
1300
1301
1302

To expand our benchmark beyond human-authored questions, we employed Large Language Models (LLMs), specifically Gemini 2.0 Flash, Gemini 1.5 Pro, GPT-4.0, and Claude 3.7 Sonnet, to extract additional questions from 212 carefully selected quantum computing papers. This automated extraction process generated an initial pool of over 8,000 candidate questions, each with six potential answer options.

1303
1304
1305

The filtering process involved multiple stages. First, we identified and removed questions that strayed from quantum computing into adjacent domains. Examples of filtered questions include:

1306
1307
1308
1309

Example: Filtered Question - General Cybersecurity

Question: Which encryption protocol is most commonly used for securing HTTP connections?

1310
1311
1312
1313
1314

- A. TLS/SSL
- B. SSH
- C. IPSec
- D. WPA2

1315
1316

Reason for filtering: While encryption is relevant to quantum cryptography, this question addresses classical network security without quantum computing connection.

1317

1318
1319

Example: Filtered Question – Mathematical Modeling

1320
1321

Question: In the analysis of an ordinary differential equation system, what does a non-positive log-norm of the coefficient matrix imply?

1322
1323
1324
1325
1326

- A. The system is unstable for all inputs
- B. The matrix has only imaginary eigenvalues
- C. The solution decays or remains bounded over time
- D. The matrix is diagonalizable over the complex field

1327
1328
1329
1330

Reason for filtering: While this concept appears in resource analyses for quantum-inspired algorithms, it tests classical stability theory in differential equations and does not assess quantum computing knowledge.

1331
1332
1333
1334

After removing duplicate questions, filtering irrelevant content, and conducting manual quality review, we retained 4,400 high-quality questions. For each retained question, we selected the four most relevant answer options from the initial six, ensuring each question had one correct answer and three well-crafted distractors that effectively test quantum computing knowledge.

1335

A.3 QUESTION TRANSLATION AND MULTILINGUAL VALIDATION

1336
1337
1338
1339
1340

For the QC500 subset, we created Spanish and French translations using a multi-stage process. We employed the same four LLMs (Gemini 2.0 Flash, Gemini 1.5 Pro, GPT-4.0, and Claude 3.7 Sonnet) to generate initial translations. A typical translation prompt was structured as follows:

1341
1342
1343
1344

"Translate the following quantum computing question from English to French, maintaining technical accuracy and appropriate scientific terminology:
[Question and answer options]"

1345
1346
1347
1348
1349

For each question, we collected translations from all four models and selected the most accurate version. This selection was then reviewed by individuals proficient in both languages who verified technical terminology and ensured conceptual accuracy. The translation process preserved the semantic content while adapting to language-specific conventions for scientific terminology.

1350 Examples of translated questions include:
 1351

1352 French Translation Example 1

1353
 1354 **Question:** Pourquoi les attaques par impulsion à grande échelle sont-elles difficiles à réaliser
 1355 dans les systèmes partagés ?

1356 A. Elles dépendent d'un accès chiffré aux qubits
 1357 B. Elles nécessitent un accès à la machine au niveau administrateur
 1358 C. Elles requièrent de nombreux qubits, auxquels les utilisateurs n'ont généralement
 1359 pas accès
 1360 D. Elles échouent si la machine est calibrée

1361 **Answer:** C

1362 French Translation Example 2

1363
 1364 **Question:** Pourquoi les algorithmes quantiques paramétriques sont-ils difficiles à vérifier
 1365 sémantiquement ?

1366 A. Ils utilisent des paramètres fixes définis dans le matériel
 1367 B. Ils reposent uniquement sur un post-traitement classique
 1368 C. Leurs paramètres entraînés manquent d'interprétabilité inhérente
 1369 D. Leur structure est identique pour tous les ensembles de données

1370 **Answer:** C

1371 Spanish Translation Example 1

1372
 1373 **Question:** ¿Cuál es la principal diferencia entre la privacidad diferencial clásica y la privaci-
 1374 dad diferencial cuántica?

1375 A. La PD cuántica extiende las garantías de privacidad a estados cuánticos indistin-
 1376 guibles utilizando distancias de traza
 1377 B. La PD cuántica elimina la necesidad de análisis probabilístico
 1378 C. La PD cuántica se aplica solo a registros de qubits entrelazados
 1379 D. La PD cuántica se impone eliminando los resultados de medición de qubits

1380 **Answer:** A

1381 Spanish Translation Example 2

1382
 1383 **Question:** ¿Qué algoritmo clásico se utiliza comúnmente después del paso cuántico del
 1384 Algoritmo de Shor?

1385 A. Algoritmo de Dijkstra
 1386 B. Expansión de fracciones continuas
 1387 C. Integración de Monte Carlo
 1388 D. Búsqueda binaria

1389 **Answer:** B

1390 A.4 QUESTION FORMAT DIVERSIFICATION

1391 To evaluate models' performance across different cognitive tasks, we expanded our benchmark with
 1392 true/false and open-ended questions. For this expansion, we selected 40 additional research papers
 1393 to ensure diverse content and avoid repetition. Both LLMs and human experts generated questions
 1394 following similar protocols to the initial question creation phase.

1404

1451
1452
1453
1454
1455
1456
1457
1404 This process yielded 416 true/false questions and 421 open-ended questions. True/false questions were created by converting factual statements into binary assessments:

True/False Question Examples

Question: The Bloch sphere is a geometrical representation of pure quantum states of a two-level quantum mechanical system.

Answer: True

Question: Dirac notation can only represent pure states, not mixed states.

Answer: False

Question: The E91 protocol is based on entangled particles and provides a method for secure quantum key distribution.

Answer: True

Question: Quantum error correction codes do not require any additional qubits beyond the physical qubits used to represent the logical qubit.

Answer: False

Open-ended questions were designed to assess deeper understanding and explanatory capabilities:

Open-Ended Question Examples

Question: What is the no-cloning theorem and its implication for quantum information?

Question: How does the Heisenberg uncertainty principle affect the measurement of quantum states?

Question: In the context of quantum states, what distinguishes a pure state from a mixed state?

Question: Explain the significance of the CNOT gate in quantum entanglement.

Sample Answer: The CNOT gate, or controlled-NOT gate, is crucial for creating entanglement between two qubits, as it flips the state of the target qubit only if the control qubit is in the state $|1\rangle$.

For each open-ended question, we developed sample answers to facilitate consistent evaluation across different models. These questions were assessed manually to determine whether model responses captured the essential concepts and technical accuracy required for each topic.

A.5 HUMAN PERFORMANCE BASELINE STUDY

Table 6 reports accuracies for the first 20 respondents. Scores range from 23.3% to 86.7%, with an overall average of 57.2%. Participants with 5+ years of experience achieved an average of 79.4%, providing a reference point for expert-level performance. Education level shows a clear pattern: all PhD-trained participants scored at or above 73.3%, while no BS-level participant reached 60%. These results provide a concrete reference distribution for interpreting model-human comparisons in the main results.

REFERENCES FOR EACH TOPIC

Table 7 lists the literature sources and citation coverage for all seven benchmark topics. Rapidly developing areas such as quantum cybersecurity and quantum machine learning rely heavily on the most recent papers to capture ongoing advances, whereas foundational categories such as quantum theory and quantum error correction draw on a broader historical record to reflect the principles that remain central to the discipline. This distribution ensures that the benchmark balances up-to-date research with enduring theoretical foundations, giving a clear view of how source material supports each topic area.

1458	Participant	Education	Experience	Age Group	Score	Accuracy
1459	P1	MS	2–5 yrs	25–35	19/30	63.3%
1460	P2	BS	<1 yr	18–25	14/30	46.7%
1461	P3	PhD	5+ yrs	35–45	25/30	83.3%

A.6 FINE-TUNING METHODOLOGY

Our fine-tuning experiments employed Low-Rank Adaptation (LoRA) to efficiently adapt smaller language models to quantum computing knowledge while maintaining computational feasibility. The implementation utilized a carefully selected subset of 4,167 question-answer pairs from the QC-Bench dataset for training, with an additional 1,000 questions reserved for evaluation. The training data was formatted as concatenated prompt-completion pairs to maximize learning efficiency within context length constraints. We applied LoRA with rank 8 and alpha 16, specifically targeting the attention projection matrices (q_proj, k_proj, v_proj, o_proj) which are critical for knowledge representation. The training configuration employed a batch size of 4 with gradient accumulation over 4 steps, resulting in an effective batch size of 16, paired with a conservative learning rate of 1e-4 using the AdamW optimizer. To ensure stable convergence, we implemented 50 warmup steps followed by training for a single epoch, which empirical testing showed was sufficient to achieve knowledge transfer without overfitting. The models were loaded in FP16 precision to reduce memory requirements while maintaining numerical stability, with automatic device mapping to optimize GPU utilization. Early stopping was monitored through validation accuracy computed every 200 steps, though most models converged within the single epoch. This approach resulted in training only approximately 0.5-2% of total model parameters, demonstrating that quantum computing knowledge can be effectively incorporated through targeted parameter updates rather than full model retraining.
