Abstract

Previous attempts to build effective semantic parsers for Wizard-of-Oz (WOZ) conversations suffer from the difficulty in acquiring a high-quality, manually annotated training set. Approaches based only on dialogue synthesis are insufficient as dialogues generated from state-machine based models are poor approximations of real-life conversations. Furthermore, previously proposed dialogue state representations are ambiguous and lack the precision necessary for building an effective agent.

This paper proposes a new dialogue representation and a sample-efficient methodology that can predict precise dialogue states in WOZ conversations. We propose a precise, complete, and executable dialogue representation called ThingTalk+, which captures all information an agent needs to respond properly. Our training strategy is sample-efficient: we combine (1) few-shot data sparsely sampling the full dialogue space and (2) synthesized data covering a subset space of dialogues generated by a succinct state-based dialogue model. The completeness of the ThingTalk+ language is demonstrated with a fully operational agent, which is also used in training data synthesis.

We demonstrate the effectiveness of our methodology on MultiWOZ 3.0, a reannotation of the MultiWOZ 2.1 dataset in ThingTalk+. ThingTalk+ can represent 98% of the test turns, while the simulator can emulate 85% of the validation set. We train a contextual semantic parser using our strategy, and obtain 79% turn-by-turn exact match accuracy on the reannotated test set.

1 Introduction

Virtual assistants and task-oriented dialogue agents are transforming how consumers interact with computers. This has led to active research on dialogue state tracking networks (Ren et al., 2019; Zhou and Small, 2019; Zhang et al., 2019; Chen et al., 2020; Heck et al., 2020), and even full neural networks that track dialogue states, implement dialogue policies, and generate agent utterances (Williams and Zweig, 2016; Eric and Manning, 2017; Zhang et al., 2019; Peng et al., 2020; Hosseini-Asl et al., 2020).

Dialogue state tracking on Wizard-of-Oz task-oriented conversations, where humans are asked to simulate both the agent and the user, has proven to be challenging. For example, despite multiple rounds of manual annotation, the MultiWOZ multi-domain task-oriented dataset still contains significant errors which hamper the development of accurate semantic parsers (Zang et al., 2020; Han et al., 2020; Ye et al., 2021). An approach to bypass manual annotations is to generate dialogues using a simulator and then manually paraphrase them (Shah et al., 2018). Unfortunately, as we shall show in this paper, such dialogue simulators do not exercise many of the possible dialogue flows seen in Wizard-of-Oz conversations. This gap is likely to widen with real-life conversations.

Given the many attempts to creating accurate semantic parsers for the MultiWOZ data set, this paper takes a fresh look at the problem of understanding Wizard-of-Oz conversations. We observe...
two fundamental flaws with the current approach. Previously proposed state representations such as slot-value pairs and the recently proposed hierarchical forms (Cheng et al., 2020) do not capture critical details in the user utterances, such as logical “or” and negation. Even if the semantic parser is 100% accurate, the agent will not be able to satisfy the user’s request. Second, it is easy to make errors. The existing slot representation is ambiguous, so it is not possible to be consistently correct. This leads to poor quality of annotation.

This paper shows that it is possible to create a precise and accurate semantic parser for Wizard-of-Oz conversations in a sample-efficient manner. We introduce the MultiWOZ 3.0 dataset, a reannotation of the full test set and partial validation set of MultiWOZ 2.1 (Eric et al., 2019), using a new, more precise formal representation. The contributions of this paper include:

1. A precise, complete, executable ThingTalk+ representation for dialogues. Whereas the ThingTalk programming language was previously proposed to represent just a single utterance (Campagna et al., 2019), ThingTalk+ is a full formal representation of a dialogue, including multiple turns of user input, results from the user request (such as a database lookup or API invocation), and the agent’s response. We show that it is precise enough to capture 98% of the turns in MultiWOZ 3.0.

2. We show that we can obtain a high-quality synthetic training data set with a simulator that adopts the ThingTalk+ representation. The precision of ThingTalk+ makes it possible to generate the many distinctively different dialogue paths that mirror those in the WOZ conversation. Our experiment shows that our simulator can generate 85% of the user turns.

3. We show that by leveraging synthesized dialogues represented in ThingTalk+, we can train an effective semantic parser for WOZ conversations. This is significant since it is difficult to annotate dialogues accurately. ThingTalk+ does not make it easier to annotate, but it is unambiguous. We annotate manually only a few-shot training set, and rely on the synthesis for the rest. The few-shot training data is 2% of the typical amount of annotated data.

The few-shot training samples in ThingTalk+ help the semantic parser generalize from the simulated dialogues to WOZ conversations. Whereas the state-machine based simulator can only generate a subset of the states representable by ThingTalk+, ThingTalk+ can precisely represent nearly all WOZ data.

Our novel contextual semantic parser, described in Section 5, obtains a turn-by-turn accuracy of 79% on MultiWOZ 3.0. Note that the model can generalize to utterances that fall out of the realm of simulation.

2 Related Work

State Representation for DST Dialog State Tracking is the task of predicting a formal representation of a conversation. The standard representation used in DST contains the values of all slots mentioned in the dialogue (Asri et al., 2017; Budzianowski et al., 2018). This is inadequate in practice. First of all, the definition is ambiguous, as it could mean “all slots mentioned by the user” or “all slots mentioned by either the user or the agent”. This has lead to inconsistency in annotation. Second, the representation does not track the comparison or logical operators in the request, so it cannot model complex queries.

Recently, Cheng et al. (2020) proposed adopting a formal representation for both the user and agent state, using the TreeDST representation. TreeDST was built to support only dialogues synthesized and paraphrased from a compatible state machine, while ThingTalk+ supports the full generality of Wizard-of-Oz conversations.

Data Acquisition for DST In recent years, a number of very large DST datasets have been released (Budzianowski et al., 2018; Byrne et al., 2019; Rastogi et al., 2019). The preferred technique to acquire such datasets is through Wizard-of-Oz (Kelley, 1984), a technique in which two humans are instructed to converse with each other, with one person taking the role of the agent. WOZ datasets are expensive, and the annotation quality is poor. A different approach synthesizes a large corpus of dialogues using a state machine, then employs crowdworkers to paraphrase them. Paraphras-
thing has been applied to semantic parsing (Wang et al., 2015) and dialogues (Shah et al., 2018; Rastogi et al., 2019; Cheng et al., 2020). Paraphrased datasets have less variety than WOZ, and crowdsourced paraphrases are also expensive. Our approach has a significant cost advantage, while matching the variety of WOZ dialogues.

Campagna et al. (2020) found that using data synthesized from a small finite state machine, it is possible to increase the accuracy of DST in the transfer learning setting. Later, Yu et al. (2020) proposed using synthesized data to pre-train a DST model, using a different objective function. They showed modest improvements in MultiWOZ 2.1, using the full training set. We instead propose using the same fine-tuning objective for both synthesized and few-shot annotated data.

3 The ThingTalk+ Dialogue Language

The ThingTalk+ Dialogue Language is designed to capture formally all relevant information in task-oriented dialogues to interpret what the user says next. This includes the user utterances, the result of the user requests, as well as the agent’s replies.

To see why the results and the agent’s reply are needed, consider the example in Fig. 1. The user has previously asked for a cheap restaurant, and now asks “Do you have anything with Indian food?”. In the example, the agent noted that there are many cheap restaurants available, so it is likely that the user wants both “Indian” and “cheap”. This is reflected in the query that the command maps to. Conversely, had the agent responded that there are no cheap restaurants, it is likely that the user no longer cares about finding a cheap and only wants Indian. The user query thus would be just:

Exec : Restaurant.food = “indian”

This illustrates that the meaning of the user utterance depends on the result and the agent’s response, so we must include them in the formal dialogue. The previous slot-based representation captures only what is mentioned by the user; it is not precise enough to handle this example.

Formally, ThingTalk+ represents (1) the user state \( u \in U \) with the semantics of a single user turn, (2) the agent state \( a \in A \) with the semantics of the single agent turn, and (3) the formal dialogue \( d \in D \) to capture all information necessary to interpret the user utterance. In this section, we provide the detailed definition of each component. The formal syntax is included in the appendix.

(a) Sorting and ranking in ThingTalk+

Agent: There are 14 trains that arrive by 12:45. What time would you like to leave?

User: What’s the latest train i can take that will still get me there by 12:45?

\[ u_1 = \text{Exec} : \text{sort}(\text{arrive_by desc of Train}, \text{arrive_by} \leq 12.45 \& \& \ldots)[1] \]

(b) Projection and logical operators in ThingTalk+

User: I think i would like to visit both churchill and magdalene colleges. May I have their phone numbers?

\[ u_1 = \text{Exec} : [\text{phone} of \text{Attraction}, \text{name} = \text{“churchill”} \| \text{name} = \text{“magdalene”}] \]

Figure 2: ThingTalk+ representations of user utterance examples in the MultiWOZ 3.0 validation set. \( u_1 \) denotes the user state.

Agent: […] Would you like me to make you a reservation?

User: Yes, please make a reservation.

\[ u_1 = \text{Exec} : \text{Restaurant.MakeReservation} (\text{name} = \ldots) \]

Agent: What day and time?

\[ u_1 = \text{SlotFill} : \text{book_day.book_time} \]

Restaurant.MakeReservation (name = \ldots)

Figure 3: Examples of a user continuing or abandoning a transaction, adapted from the MultiWOZ 3.0 validation set. The user state \( u_2 \) denotes this fact by propagating or discarding the action. \( u_1 \) is the agent state.

User State. The formal semantics of a user turn is represented by a user state \( u \in U \), which consists of an abstract dialogue act and, for dialogue acts that provide or request information, a program in the ThingTalk language. A program is a sequence of statements: either database queries, or actions with side effects (such as making a reservation). Queries specify the domain of interest and can use the standard relational operators: selection, projection, aggregation, sorting. Actions specify the domain, the action name, and the parameters necessary for the action. Note that ThingTalk only represents programs, while ThingTalk+ represents user states including dialogue acts. User state examples in Figures 1 and 2 with abstract act “Exec” are all queries, while the example in Fig. 3 uses the action “Restaurant.MakeReservation”.

The user state includes new statements that are implied by the current utterance and statements that the user has previously mentioned and is still interested in pursuing (Fig. 3). Note that a single user utterance may map to multiple ThingTalk+ statements, possibly in different domains.
Agent State. Analogously, each agent turn has a formal agent state $a \in A$ representation, which is computed by the agent policy. The agent state includes an abstract dialogue act, as well as an optional agent statement, which either requests some slots from the user, proposes a new statement to the user, or asks the user to confirm an action.

Formal Dialogue Representation. A formal dialogue $d \in D$ captures all the information in the conversation needed to interpret the user utterance. Specifically, it contains the current agent state, the accumulated results of executing the user statements in previous turns, and the user statements that the user has asked to execute but that are missing some required parameters. The results for queries are the items retrieved from the database; the results for actions are returned by the API call.

4 Simulator-Agent Architecture

To synthesize data for training, we propose a simulator-agent architecture. The state-based simulator takes the role of the human user. The same agent that would be used at deployment time is used during synthesis. The agent is built based on the semantics of ThingTalk+, not just the simulator. It can respond correctly to any dialogue $d \in D$ representable in ThingTalk+. On the other hand, the simulator samples a subset space $D_{\text{Sim}} \subset D$. We refer to dialogues in $D_{\text{Sim}}$ as in-simulation; other dialogues are out-of-simulation.

Formally, the architecture has three components:

Agent $(d, u) : D \times U \rightarrow D$: an agent that accepts a formal dialogue $d \in D$, and the user state $u \in U$ representing the last user utterance, to produce a new dialogue $d' \in D$. The agent guarantees that if $d \in D_{\text{Sim}}$ then $d' \in D_{\text{Sim}}$.

Sim $(d) : D_{\text{Sim}} \rightarrow X \times U$: a simulator that accepts an in-simulation dialogue $d \in D_{\text{Sim}}$, and creates non-deterministically a new user utterance $x \in X$ and its user state $u \in U$.

CSP $(d, x) : D \times X \rightarrow U$, a contextual semantic parsing model that accepts a dialogue $d \in D$, which may not be in $D_{\text{Sim}}$, and a user utterance $x \in X$ to predict the user state in $U$.

In this section, we describe how the components are used to synthesize training data and build a functional dialogue agent.

4.1 Training Data Synthesis

We synthesize training data for CSP as follows:

$$\text{Syn}(d) : D_{\text{Sim}} \rightarrow D_{\text{Sim}} \times X \times U$$

the synthesizer accepts a dialogue $d \in D_{\text{Sim}}$ and returns a training sample produced by using Sim to generate a possible user utterance and a resulting in-simulation dialogue to be predicted, then applying the Agent to continue:

$$\text{Syn}(d) = (d', x, u), \text{ where}$$

$$(x, u) = \text{Sim}(d), d' = \text{Agent}(d, u)$$

Starting with a null dialogue, we iteratively use Syn to synthesize training samples. During synthesis, the agent is called in a mock execution environment with no side effects, and it uses a non-deterministic policy that generates many possible agent behaviors. It is helpful to include many agent behaviors because it helps model the human WOZ agent.

Following Campagna et al. (2020), both the simulator and the agent policy are implemented using a domain-independent state machine which includes many natural language templates for user and agent utterances. Using the templates and a few natural language phrases for each slot, we can quickly generate dialogues for any new domain.

4.2 Deployment

After training, the same agent can be used at deployment time to reply to the real user.

$$\text{Deploy}(d, x) : D \times X \rightarrow D$$

given the current dialogue, a deployable system uses CSP to map the next user utterance to a formal dialogue, which is then used by Agent to continue the dialogue. Let $d_0$ be the empty dialogue and user input $x_1, x_2, \ldots$

$$d_i = \text{Deploy}(d_{i-1}, x_i)$$

$$= \text{Agent}(d_{i-1}, \text{CSP}(d_{i-1}, x_i))$$

4.3 Out-of-simulation Dialogues

While the simulator can cover only the most common dialogue paths, ThingTalk+ is designed to be general, covering many more possible dialogues. To improve generality, the CSP is trained not only with simulated dialogues but also few-shot data annotated with the full expressiveness of ThingTalk+. Correspondingly, the agent is written to handle the full representation of ThingTalk+. This design makes our parser and agent more robust than...
User: Please book a table for 5 at 14:30 on wednesday at Royal Spice. I also need to find a place to stay.

\[ u_1 = \text{Exec: Restaurant.MakeReservation} (\text{name} = \text{“royal spice”}, \text{book_people} = 5, \text{book_time} = 14:30, \text{book_day} = \text{wednesday}); \text{Hotel}; \]

Agent: I was able to book your table successfully. Your reference number is kqmxil0z. Now, what type of accommodations are you looking for today?

Figure 4: Example of out-of-simulation dialogue, adapted from the MultiWOZ 3.0 test set, where the same turn mentions two domains. The simulator never generates such a turn but the agent can reply to it.

To reduce the length of the input, the formal dialogue is truncated before feeding to the model: only the last executed query and action in each domain are kept, and the rest is discarded. Previous statements are no longer relevant; information that is still relevant is carried over in the last statement. Additionally, we encode at most one result per query. We observe that the user uses either a co-reference to refer to the only/first choice, or uses the entity name. The model is trained to copy entity names from the user utterance; the name is normalized to the ontology in a subsequent step.

We use BART-Large, with about 400M parameters. We train it with token-level cross-entropy loss and teacher forcing. Hyperparameters are included in the appendix.

5.2 Training Data

Data Synthesis. We use Syn to synthesize an initial set of training dialogues, covering all possible combinations of slots at each turn, and many possible paths in \( \mathcal{D}_{\text{Sim}} \).

Automatic Paraphrasing. We apply automatic paraphrasing to increase the variety of natural language in each turn (Xu et al., 2020). We use a pretrained BART model (Lewis et al., 2019), fine-tuned on the ParaBank2 general-purpose paraphrasing dataset (Hu et al., 2019). Each user utterance is paraphrased individually. We apply filtering to ensure that the user state does not change for each utterance: each paraphrased utterance, with its associated formal dialogue, is passed to a model trained on synthesized data; the utterance is discarded if the model predicts a different user state than the annotation before paraphrasing.

Few-Shot Fine-Tuning. To expose the model to the variety in real-world data, we fine-tune the model with a small number of manually annotated dialogues.

Self-Training. Acquiring large fully-annotated WOZ datasets is challenging, because annotations are often erroneous. Acquiring unannotated WOZ datasets, on the other hand, is easier. To use such data, we propose using self-training (McClosky et al., 2006; Einolghozati et al., 2019; Zoph et al., 2020). We apply the model fine-tuned on few-shot data to unannotated input, create a training set using the predicted result as annotations, and use that to further fine-tune the model.
The slot values in our new test set differ from the original annotations in 83% of the turns. This is not surprising because others have already found problems in MultiWOZ 2.1 (Zhou and Small, 2019; Zang et al., 2020; Han et al., 2020), and because ThingTalk+ and the existing annotations adopt different conventions for when a slot should be included. We found mistakes in the annotations, inconsistent normalization of names, and inconsistent annotation of slots offered by the agent. We dropped 1% of test turns due to unrecoverable human errors, such as the user acting as the agent.

We use four datasets for training:

- **Synthesized** dataset, generated using our state-machine-based simulator and agent, consisting of 1.5M dialogues across all five domains. The state machine has 20 abstract transitions for the agent, and 43 for the user.
- **Paraphrase** dataset, obtained by automatically paraphrasing the synthesized data.
- **Few-Shot** dataset, a split of 168 dialogues from the original validation set. This amounts to 2% of the original training set. Another 265 dialogues in the original validation set are used as the 3.0 validation set.
- **Self-Trained** dataset, obtained by self-training on the MultiWOZ training set.

Dataset statistics are included in the appendix.

We use the Genie Toolkit for data synthesis (Campagna et al., 2019) and the Huggingface Transformers library for the model (Wolf et al., 2019). Code and data will be released open-source upon publication.

### 6.2 Precision of ThingTalk+

ThingTalk+ is designed to precisely cover the semantics of Wizard-of-Oz dialogues. We first observe that ThingTalk+ captures the semantics of the sentences well: it can represent the validation set in its entirety, and 99.8% of the user utterances and 97.6% of the agent utterances in the test set are representable. Overall, that comprises 97.7% of the test turns. ThingTalk+ cannot represent, for example, out-of-domain questions, questions that cannot be answered using the given database, and agent utterances such as asking the users to wait.

User utterances in the test set that cannot be represented are simply counted as errors, while agent utterances that cannot be represented as marked with a single “invalid” dialogue act, which is given as input to the neural model. The model can choose...
Comparison with previous representations In Table 1 we compare ThingTalk+ with two existing state representation: the slots and values representation used in MultiWOZ, and the TreeDST representation proposed by Cheng et al. (2020). For each feature, we also include the frequency the feature is used in the MultiWOZ 3.0 test set. Note that MultiWOZ was constructed with slots and values in mind, and this is reflected in the crowdworkers instructions. Thus, the use of the more sophisticated features in MultiWOZ is a strong indication of their importance in natural conversations.

ThingTalk+ is unique in representing user queries and commands as executable database queries and API calls. (1) It is easier to annotate manually. Other approaches require annotators to be familiar with the semantics of each domain, whereas annotators just need to learn the database query syntax and can annotate for different domains. (2) The implementation of the agent needs only to execute ThingTalk+ statements; no custom per-domain logic is necessary. Additionally,ThingTalk+ can represent the full generality of WoZ conversations. For example, ThingTalk+ can represent turns that have no request, at the beginning and end of the conversation, while TreeDST cannot. This oversight highlights the need to design the representation based on real conversations.

One feature present in the previous representation that we drop from ThingTalk+ is the precise slots mentioned by the agent. For example, in response to a user asking for a restaurant, the agent may mention the restaurant “name” and “address.” Such slots do not affect the interpretation of the user utterance. Removing them from the agent state coalesces many more utterances into the same state, and allows to approximate more complex human agent utterances, increasing the state coverage and boosting the accuracy of the semantic parser.

6.3 Accuracy on the MultiWOZ 3.0 Test Set
Our first experiment evaluates how well our CSP model can understand the user utterances in the MultiWOZ 3.0 dataset on four metrics. Exact match accuracy requires the predicted user state to match identically the annotation. Slot accuracy requires the slots provided by the user in the predicted user state to match the annotation, ignoring comparison operators, requested slots, and the dialogue act.

Turn-by-turn accuracy assumes that the gold dialogue up to the current turn is available as input. Dialogue accuracy requires predicting the correct state for all the previous and current turns of a given dialogue. This is a challenging but meaningful metric because in practice, once the model fails, the conversation diverges from the WOZ dialogue.

We train our CSP model on the combination of Synthesized and Paraphrased sets, fine-tune it on the Few-Shot training set, and fine-tune it again on the Self-Trained set. Our model achieves a 79.2% turn-by-turn accuracy and 44.1% dialogue accuracy in exact match (Table 2).

To understand the role of the synthesized data, we removed all synthesized data, and train with only the few-shot, manually annotated data. The synthesized data improves the accuracy by 5.5% turn-by-turn and 8.4% for dialogue accuracy. This shows that the low-cost automatically generated training data is effective.

We performed an ablation study on the validation set to evaluate the components of our training strategy (Table 2). We first observe that the validation accuracy is higher than the test accuracy, because we used the validation set to refine our synthesis. Training with only synthesized data already delivers a respectable 61.8% turn-by-turn accuracy; with the augmentation of auto-paraphrasing data, turn-by-turn accuracy improves 0.1%, and dialogue accuracy improves 0.4%.

The few-shot training alone delivers a high accuracy of 75.6%. When the model trained on synthesized and paraphrased data is fine-tuned with few-shot data, the accuracy is 81.0%, showing that these two approaches complement each other. Self-training further improves the turn-by-turn accuracy by 0.4%, with 1% better dialogue accuracy.

64. Generalization of the Dialogue Model

Our strategy is to handle the complexity of Wizard-of-Oz dialogues with a combination of simulated dialogues and few-shot training samples to teach generalization beyond simulated dialogues. We analyze the validation set to understand the difference between the simulated dialogues and the Wizard-of-Oz dialogues, and its effect on accuracy.

The results are shown in Table 3. The validation set is divided in:

1. Trained: 15.5% of the validation set turns share the same formal dialogue and user state with some sample in training (ignoring the slot values). Accuracy obtained: 93.1%.
2. In-simulation: 69.7% of the validation set turns can be represented by the simulator: the formal context is contained in $D_{\text{sim}}$, and the user state can be generated by the simulator. Accuracy obtained: 82.4%.
3. Out-of-simulation: 14.7% of the validation turns require the model to generalize beyond $D_{\text{sim}}$, either through few-shot or its own generalization capabilities. Accuracy obtained: 62.7%.

Our synthesizer covers the Wizard-of-Oz conversations well. Even though our simulator and agent are built using a state machine with only 54 user transitions and 24 agent transitions, 85.2% of the validation set is in-simulation.

Research that trains and validates on simulated data is missing a non-trivial population of Wizard-of-Oz dialogues. We found that 14.7% of the validation turns are representable in ThingTalk+, but are out-of-simulation.

Our training strategy generalizes beyond the simulated dialogues. For the out-of-simulation turns, our model achieves an accuracy of 62.7%. The model can generalize well on validation turns where the agent state is unseen in training, achieving 66% accuracy. This result speaks to the strength of using a formal representation of the agent, which avoids interpreting untrained agent utterances.

The model also reacts well to strong signals in the user utterance. The model achieves 84.1% accuracy when the user switches domains unexpectedly, and 73.3% accuracy when the user starts issuing slots for the action before completing the query.

Finally, when the user issues a command over two domains at once, the model achieves 16.7% accuracy. When the user abandons a booking transaction mid-way, the model achieves 25% accuracy. These kinds of out-of-simulation states are also rare in the few shot training set. The model can generalize, but it is biased by the common case shown by the training data.

7 Conclusion

This paper presents a sample-efficient methodology, based on the new ThingTalk+ representation, to predict precise dialogue states in Wizard-of-Oz conversations. We achieve a turn-by-turn exact-match accuracy of 79.2% on the MultiWOZ 3.0 dataset, with only a manually annotated data set 50x smaller than the original.

The proposed ThingTalk+ representation is precise, complete, and executable. It is precise enough to cover 98% of the dialogue turns in MultiWOZ. The precision enables automatic synthesis of dialogues covering 85% of the MultiWOZ data set. ThingTalk+ is complete and executable, as evidenced by a fully working agent that can simply execute ThingTalk+ queries without referring to the user input. Furthermore, the agent can handle dialogue flows beyond those that can be simulated.

The accuracy is achieved with a contextual semantic parser (CSP) where the dialogue context is represented in ThingTalk+ rather than the natural language dialogue history. It is trained first with auto-paraphrased synthetic data, fine-tuned with the few-shot annotated data, then self-trained.

In summary, this paper shows that with ThingTalk+, we can predict WOZ dialogues accurately with mostly training data generated from a state machine. Our methodology thus combines the best of the WOZ and M2M approaches, as it can handle the more realistic WOZ dialogues, while having a low data acquisition cost like M2M.
8 Ethical Considerations

We envision that our training strategy will broaden the availability of task-oriented agents for tasks and populations not currently covered by existing large-scale datasets, due to its low annotation requirement. We will open-source tool set designed around our representation for bootstrapping affordable contextual semantic parsers for new domains.

Our agent was tuned and evaluated on the MultiWOZ benchmark. MultiWOZ is a crowdsourced Wizard-of-Oz dataset; WOZ datasets are known not to fully represent real-world conversations (Ganhostra et al., 2020). Further research is needed before a dialogue agent based on our methodology can be deployed in the real world. Additionally, the current version of the agent was tuned for English; future work should investigate techniques to automatically localize a contextual semantic parser, analogously to prior research done for single-turn semantic parsers (Moradshahi et al., 2020).

Our training strategy replaces manual annotation of data with automatically obtained data, which requires some additional amount of computation time. The additional computation can be an environmental concern. In practice, such additional compute is small: data synthesis runs in 5 hours on a single machine with no GPUs; the paraphrase dataset can be obtained in about 5 hours on a machine with 4 Nvidia T4 GPUs; training completes within 8 hours on a machine with one Nvidia V100; self-training requires 2 hours on a single Nvidia T4 GPU, and fine-tuning is another 1.5 hours on one Nvidia V100. Overall, the whole process is done with about 22 hours of compute time, well below the cost of human annotation of equivalent amounts of data. We note that the large amount of synthetic data poses no challenge to convergence in practice, so increasing the amount of synthesized data has little effect on the compute cost.

The manually annotated portion of our dataset was obtained from the previously released MultiWOZ 2.1 dataset, a crowdsourced dataset. No crowdsourcing was employed in this paper; the data was annotated by the authors.

Value $v$ : <constant>

A.2 Agent Definition

The agent is a function $Agent(d, u) = d'$ that computes the new formal representation of the entire dialogue. The representation is constructed incrementally, starting from the initial dialogue $d_0$ which is empty.

Let $d = (a, r, s) \in D$ and $u = (ua, s_u) \in U$ be the two inputs to the agent. The agent computes the new agent state $a$ as follows:

$$r_u, i_u = \text{Execute}(s_u)$$

$$a' = \text{Policy}(ua, r || r_u, i_u)$$

$$d' = (a', r || r_u, i_u)$$

where $||$ denotes concatenation. The Execute function calls the ThingTalk runtime to execute the statements in the user state, $s_u$. It returns (1) the results $r_u$ by executing all statements in $s_u$ whose required parameters are available, (2) the rest of the (incomplete) statements, $i_u$. The Policy function determines the agent state $a'$ from the user state $ua$. all the results $r_u$ appended to previous results $r$, and $i_u$. The agent returns the new dialogue $d'$ with the new agent state, all the results and the new incomplete statements. The incomplete statements $s$ in $d$ are discarded. If the user has not changed topics, information in $s$ is incorporated in $s_u$.

B Training

B.1 Preprocessing

We apply the same preprocessing used by TRADE (Wu et al. 2019) to the input utterances. We also use a rule-based preprocessor to identify time expressions, and replace them with placeholder tokens. All slot values in the result and agent states that have string or time type are replaced with a placeholder when input to the model.

We normalize all slot values in the user state to match the utterance, regardless of typos. When comparing the slot values for equality, we normalize entity names via a database lookup.

B.2 Hyperparameters

Our model uses a BART large model (with the “bart-large” pretrained model) which has 400 million trainable parameters. We use the Adam optimizer, with the Transformer learning rate schedule (800 iterations of warm-up, 0.04 multiplier).

We train our model for 50,000 gradient updates on the synthesized data and choose the model with the highest validation exact-match accuracy. We then fine-tune that model with the few-shot training set for 15,000 gradient updates, and again choose the model with highest validation accuracy. We repeat this process for another 15,000 updates on the self-train set. Training is done on a single GPU with 16GB memory and batch size is chosen based on the length of the examples in each batch: we choose as many examples as we can fit in the GPU memory. Gradient accumulation is used to increase the effective batch size by a factor of 20.

Table 4: Statistics of our training and evaluation sets: number of dialogues, of turns, and of words. For the synthesized dataset, we do not count turns that appear identically in multiple dialogues.

D Annotated Example Dialogue

Here is an example of a dialogue generated by the simulator, between the user U and the agent A. US denotes the user state, D denotes the formal dialogue.

12
U: List good restaurants which offer Indian.
US: Exec: Restaurant, food = "Indian";
A: Do you have a specific part of town in mind?
D: SearchQuestion: area;
   Restaurant, food = "Indian"
   [ { name = "Cocum", area = west, ... },
     { name = "Rajmahal", area = east, ... },
     ... ];
U: Yes I’d like near the east.
US: Exec: Restaurant, food = "Indian" && area = east;
A: I have Rajmahal and Curry Prince.
D: RecommendTwo
   Restaurant, food = "Indian"
   [...];
   Restaurant, food = "Indian" && area = east
   [ { name = "Rajmahal", area = east, ... },
     { name = "Curry Prince", area = east, ... },
     ... ];
U: Is Curry Prince a restaurant serving Indian?
US: Exec: [food] of Restaurant, food = "Indian" && area = east && name = "Curry Prince";
A: Curry Prince serves Indian. Would you like me to book it?
D: RecommendOne: Propose Restaurant.MakeReservation(name="Curry Prince", book_people=6);
   Restaurant, food = "Indian"
   [...];
   Restaurant, food = "Indian" && area = east
   [...];
   [food] of Restaurant, food = "Indian" && area = east && name = "Curry Prince"
   [ { name = "Curry Prince", food = "Indian" } ];
U: I will take it. Please make a reservation at the restaurant on Monday at 13:00.
A: Alright, Consider your request done! Its confirmation number is ay05tzjq. Anything else for you today?
D: ActionSuccess;
   Restaurant, food = "Indian"
   [...];
   Restaurant, food = "Indian" && area = east
   [...];
   [food] of Restaurant, food = "Indian" && area = east && name = "Curry Prince"
   [...];
   Restaurant.MakeReservation(name="Curry Prince", book_people=6, book_day=Sunday, book_time=13:00)
   [ { reference_number = "ay05tzjq" } ];
U: Thanks, this is good for now. Goodbye!
US: End
