Web agents have emerged as a promising direction to automate Web task completion based on user instructions, significantly enhancing user experience. Recently, Web agents have evolved from traditional agents to Large Language Models (LLMs)-based Web agents. Despite their success, existing LLM-based Web agents overlook the importance of personalized data (*e.g.*, user profiles and historical Web behaviors) in assisting the understanding of users' personalized instructions and executing customized actions.

To overcome the limitation, we first formulate the task of LLMempowered personalized Web agents, which integrate personalized data and user instructions to personalize instruction comprehension and action execution. To address the absence of a comprehensive evaluation benchmark, we construct a Personalized Web Agent Benchmark (PersonalWAB), featuring user instructions, personalized user data, Web functions, and two evaluation paradigms across three personalized Web tasks. Moreover, we propose a Personalized User Memory-enhanced Alignment (PUMA) framework to adapt LLMs to the personalized Web agent task. PUMA utilizes a memory bank with a task-specific retrieval strategy to filter relevant historical Web behaviors. Based on the behaviors, PUMA then aligns LLMs for personalized action execution through fine-tuning and direct preference optimization. Extensive experiments validate the superiority of PUMA over existing Web agents on PersonalWAB. We release code and data at https://anonymous.4open.science/r/PersonalWAB-CDBF/.

Figure 1: Comparison between traditional Web agents (a) and personalized Web agents (b). Personalized Web agents adopt personalized data to infer implicit user preferences, assisting in understanding user instructions and performing personalized actions, leading to more intelligent Web services.

and social engagement. However, the unprecedented scale and complexity of modern Web services also present new challenges. Users, particularly the elderly groups, are overwhelmed with vast amounts of unstructured data and intricate interactions, complicating task completion on the Web [49]. To alleviate the burden of complex Web operations, Web agents have emerged as a promising solution [36] to bridge users and Web services as shown in Figure 1(a). Based on user instructions, Web agents autonomously interact with the Web to complete tasks such as information retrieval and online shopping [50], offering a convenient way to enhance efficiency and intelligence with extensive Web services.

The evolution of Web agents has undergone a significant transition from traditional agents to those powered by Large Language Models (LLMs). Traditional agents typically optimize Web navigation tasks by reinforcement learning techniques [23, 36, 50], while their context understanding and reasoning capabilities are limited, failing to generalize to complex and out-of-distribution scenarios [4]. In recent years, LLMs have demonstrated extensive world knowledge along with strong understanding, planning, and reasoning capabilities, making LLM-based Web agents a rapidly evolving direction [8, 29]. Related research has leveraged techniques such as in-context learning [17, 40, 54, 55], fine-tuning [4, 10], and reinforcement learning [30] to enhance the instruction-following capabilities of LLMs in various Web agent tasks. Notably, in addition to single-turn user instructions, some studies have explored utilizing the powerful interactive capabilities of LLMs to enable multi-turn interactions with users, facilitating conversational Web navigation and task execution [5, 25, 41].

Despite the significant success of LLM-based Web agents, they overlook the critical role of personalized data in enhancing user experience, as illustrated in Figure 1. Personalized data, such as user 59 60

profiles and historical Web behaviors, reveals implicit user prefer-139 ence, which can facilitate the understanding of user instructions and 140 enable personalized action execution. Specifically, 1) personalized 141 data can supplement user context for personalized instruction 142 comprehension. For example, when users search for a product, 143 their behavior history may reveal implicit preferences for product 144 attributes (e.g., price) that are not explicitly stated in user instruc-145 tions. Besides, 2) personalized data enables personalized action ex-146 ecution, where actions can be formulated as various Web function 147 148 calls from Web services [19, 50, 53, 57]. In this work, we abstract the Web services from various websites (e.g., , Amazon shopping web-149 site) as a diverse set of "Web functions1"; for example, the "search" 150 action can be executed by passing a textual query as function pa-151 rameters to the search API of a website. Users have varying habits 152 and preferences for Web services, leading to personalized function 153 calls with customized parameters. 154

In this light, we formulate the task of LLM-empowered per-155 sonalized Web agents, which integrate personalized user data 156 for personalized instruction comprehension and action execution, 157 aiming to align with explicit user instructions and implicit user 158 preferences derived from personalized data. Formally, given user 159 instructions alongside personalized user data (e.g., profiles and 160 161 historical Web behaviors), LLMs must infer personalized user requirements and preferences to determine which Web function to 162 call and formulate the corresponding function parameters. Subse-163 quently, the results of these function calls are returned to users. 164 However, to advance this task, the primary challenge is the lack of 165 a comprehensive benchmark for training and evaluation. 166

To bridge this gap, we construct the first Personalized Web 167 Agent Benchmark (PersonalWAB). PersonalWAB focuses on three 168 representative tasks for personalized Web agents: personalized 169 search, recommendation, and review generation on Web platforms, 170

174

171

which require LLMs to infer user preferences for task completion. Specifically, PersonalWAB is constructed by the following steps:

- 1) Personalized Data Construction: PersonalWAB adopts Amazon review dataset [12] to construct 1,000 diverse users with simulated profiles and real Web behaviors (e.g., purchase and rating).
- 2) User Instruction Creation: For the three tasks, PersonalWAB utilizes users' genuinely liked items as the ground truth for search and recommendation, and real reviews as the ground truth for review generation. PersonalWAB then uses ground truth items and reviews to synthesize corresponding user instructions.
- 3) Web Environment Implementation: To interact with the Web environment, PersonalWAB develops a series of Web functions for the three tasks.
- 4) Evaluation: PersonalWAB utilizes the ground truth in Step 2 to assess the three tasks. Notably, it not only supports single-turn evaluation but also develops an LLM-based user simulator for real-time multi-turn interaction and evaluation with users.

Extensive analysis in Section 4 validates that PersonalWAB offers a set of users with diverse profiles and behaviors, and the simulated user profiles closely align with the actual behaviors by empirical evaluation. The comparison with existing benchmarks is in Table 1.

To enable LLM-empowered personalized Web agents, we propose a Personalized User Memory-enhanced Alignment (PUMA) framework. PUMA stores users' long-term Web behaviors into a memory bank and utilizes a task-specific retrieval strategy to filter out irrelevant information, focusing only on behaviors and features relevant to the current instruction. Given the retrieved behaviors and features, PUMA then combines them with user instructions to call appropriate Web functions and generate optimal function parameters to enhance the returned results. However, the large parameter space challenges LLMs in producing high-reward parameters. To address this, PUMA designs several heuristic strategies to construct pseudo-label parameters for supervised fine-tuning (SFT) [31], enabling LLMs to generate reasonable function parameters. PUMA then uses Direct Preference Optimization (DPO) [32] to sample multiple function parameters for pair-wise optimization, better aligning with personalized user preferences. Experimental results demonstrate that PUMA significantly outperforms existing Web agents in single-turn and multi-turn personalized Web tasks, showcasing the potential of personalized Web agents to deliver more intelligent, customized, and user-centered Web services.

The key contributions in this work are as follows:

- · We are the first to formulate the task of LLM-empowered personalized Web agents, which incorporate personalized user data to achieve personalized instruction understanding and action execution, bridging users with customized Web services.
- We construct the first benchmark for LLM-empowered personalized Web agents, featuring a diverse set of users with varying profiles and behaviors, the instructions across three tasks, callable Web functions, and two evaluation paradigms.
- We propose PUMA, a novel personalized alignment framework with a user memory bank and optimization strategies to align LLMs with the task of personalized Web agents.
- · We conduct extensive experiments on PersonalWAB, showing that PUMA consistently surpasses existing Web agents, aligning better with personalized user instructions and preferences.

¹⁷² ¹"Web APIs" and "Web tools" are also used to convey similar meanings in agents. For 173 convenience, we unify these terms as "Web functions" below.

285

286

287

288

289

290

234 • Web agents. Web agents are designed to automate a variety of 235 complex Web-based tasks. Some studies focus on directly respond-236 ing to users' instructions in a single turn. MiniWoB++ [23] estab-237 lished a platform of website widgets where agents can complete 238 online tasks through keyboard and mouse. Webshop [50] introduced 239 a simulated e-commerce environment with human-written task in-240 structions. Recent studies investigate automating Web tasks under 241 more practical and complex settings, including multi-domain [4], 242 multi-hop [53], real-time interactions with Web [57], and visual UI 243 understanding [11, 19]. Numerous efforts have been made to solve 244 these problems, including fine-tuning [9, 10, 28] and prompting 245 LLMs [37, 51, 54]. 2) Another research direction involves integrating 246 user interactions into the agent's execution process. META-GUI [41] 247 introduced a dataset focused on automating actions in mobile apps 248 following conversational user instructions. RUSS [49] designed a 249 dataset to boost dialogue-centric Web navigation. Recent works 250 also focus on conversational Web navigation [5, 25] and interactive 251 information-seeking problems [2].

252 Despite advancements, prior research overlooks the dimension of 253 personalization in Web agents. A recent study simulates users with 254 distinct roles, permissions, and interaction histories [57], but these 255 roles are predefined per platform and do not require understand-256 ing user preferences nor demand the agent to adjust the execution 257 strategy according to user preferences. In this work, we first fo-258 cus on LLM-empowered personalized Web agents and propose a 259 novel framework along with a benchmark for the optimization and 260 evaluation of LLM-empowered personalized Web agents.

261 • Personalized LLMs. Personalized LLMs are designed to handle 262 user personas (e.g., , background information or historical behav-263 iors) to meet individualized needs, adapting to distinct users [43]. 264 Research in this field falls into two main categories: personalized 265 content generation and user-facing applications. 1) Personalized 266 content generation focuses on the core challenges of generating 267 personalized content. They have used openly available user data 268 on Reddit [45], Facebook, Twitter [38], and other blogging web-269 sites [18] to pre-train LLMs. Key tasks include stance classification, 270 demographic inference [39], and personalized sentiment predic-271 tion [27]. Benchmarks like LaMP [34] and LongLaMP [20] further provide datasets for evaluating personalized text classification and 273 content generation. 2) Another research direction is the practical 274 applications in real-world scenarios, starting with personalized dia-275 logue systems. Studies have built dialogue datasets by promoting 276 crowd-workers to author dialogues based on specific personas [52], 277 and by extracting user attributes from Reddit [26] and Weibo [56]. 278 Apollonion [3] dynamically updates user profiles for personalized 279 responses. Additionally, memory mechanisms [21, 24, 47] help mod-280 els recall past conversations and important events. Personalized 281 LLMs are also applied in healthcare [1, 15], education [6, 35], and 282 robotics [46] to enhance services. 283

However, previous studies have not explored personalized function calls to user-specific needs. Our work bridges this gap by emphasizing adapting agents' actions to different users by utilizing personalized user data and enabling a comprehensive assessment of agents' ability to complete several personalized tasks in Web environments.

3 Task and Benchmark

In this section, we formulate the task of LLM-empowered Web agents in Section 3.1, detail the construction of PersonalWAB in Section 3.2, and present the evaluation paradigms in Section 3.3.

3.1 Task Formulation

LLM-empowered personalized Web agents act as intermediaries between users and Web services, and we formulate the following elements in this task:

- User. Each user $u \in \mathcal{U}$ has a distinct profile P_u and the historical Web behaviors H_u . The profile P_u includes static attributes such as demographics, and H_u records the user's past Web behaviors, represented as a time-ordered sequence, $\{h_u^1, h_u^2, \ldots, h_u^N\}$. Each h_u^i denotes one Web behavior, such as a purchase or a review.
- Instruction. The user's instruction *i_u* is a natural language sentence that expresses their needs and requirements.
- Web environment. It is abstracted as a series of Web functions, denoted by \mathcal{T} . Each function $f \in \mathcal{T}$ can be invoked with an input parameter p, returning the corresponding result O_{f_p} . Notably, different input parameters will yield different function results.

Given the user instruction i_u and the personalized data P_u and H_u , LLM-empowered personalized Web agents aim to select the appreciate Web function f and determine the optimal parameter p to invoke personalized results O_{f_p} from the Web environment.

3.2 Benchmark Construction

It is challenging to gather a set of users to collect the real data on Web agent applications. Therefore, we chose to develop the benchmark using existing datasets of users' Web behaviors. Specifically, we selected the Amazon Review [12] dataset as the foundation for our benchmark, as it provides a large-scale collection of users' Web behaviors, including purchase and product rating across various categories of products. The overall pipeline for constructing PersonalWAB is illustrated in Figure A.3, which consists of three steps: *personalized data construction, user instruction creation*, and *Web environment implementation*.

3.2.1 Personalized Data Construction. This section consists of user sampling and user profile generation steps.

• User sampling. We randomly selected 1,000 users from the Amazon Review across five distinct product categories: *Electronics, Home and Kitchen, Grocery and Gourmet Food, Clothing, Shoes, and Jewelry,* and *Health and Household.* For each user, we collected all their interactions across the five categories, each containing detailed purchased product information (such as product title, price, rating, and store) and user evaluations (including ratings, titles, and comments).

To simulate realistic user behavior, we first arranged all user interactions chronologically and divided them based on timestamps into three segments: 80% as historical data, 10% for the training set, and the final 10% for the test set.

• User profile generation. We generated unique profiles for each of the 1,000 users based on their entire history of behaviors, using the language model to infer and summarize their potential profiles

346

347

Conference acronym 'XX, June 03-05, 2018, Woodstock, NY

Figure 2: Overall pipeline for constructing PersonalWAB benchmark with a real example for recommendation instruction.

(see prompt in Figure 9). Each user profile is structured to reflect the following key dimensions (see details in Figure 10):

- Basic information. This includes fundamental personal attributes such as *gender*, *age*, and *occupation*, inferred from the user's product categories and purchasing behaviors.
- Shopping preferences. This dimension captures the user's purchasing tendencies, including 1) *price sensitivity* (whether the user gravitates towards budget, mid-range, or premium products), 2) *shopping interests* (the types of products the user is most frequently drawn to), and 3) *brand preferences* (the brands most commonly referenced in the user's purchase history).
- Behavioral tendencies. We summarize the characteristics of each user's shopping behavior using LLM from the following aspects. 1) Diversity preference indicates whether the user favors trying new products or sticking with familiar ones; 2) Interaction com-plexity describes whether the user prefers concise or detailed interactions based on their review patterns; 3) Tone and style capture the emotional tone and expressive style of the user's re-views, which may affect how they engage with systems. 4) Item reference examines how often the user refers to specific products or brands in their reviews; and 5) focus aspects highlight which product features (e.g., price, average rating, brand) the user tends to prioritize in their reviews.

The user profiles will support the following personalized instruction generation (§ 3.2.2) and multi-turn evaluation (§ 3.3).

3.2.2 User Instruction Creation. As previously mentioned, organizing thousands of users to collect their real instructions poses significant challenges. To address this, we prompt the LLM to generate personalized instructions based on each user's profile and real Web behaviors. These instructions encompass three task scenarios: search, recommendation, and review.

- Search instructions: We provide the language model with a detailed user profile and product information, including key attributes like brand, category, and features, to generate instructions for searching products. The prompt is detailed in Figure 11.
 Depending on the profile, the generated search instructions vary in length, tone, level of detail regarding the product, and the specific product aspects mentioned.
- Recommendation instructions: The recommendation instruction requests generated tend to be shorter, more general, and less specific, leaving room for broader exploration. We prompt the

LLM to generate recommendation tasks with the prompt (see Figure 12), user profile, and the user's integrated products.

• Review instructions: The LLM receives both the user profile, target product information, and actual review text to generate user instructions for writing the review with users' personalized requirements. The prompt details are shown in Figure 13.

3.2.3 Web Environment Implementation. We choose to abstract and simplify the Web environment as a series of Web functions [2] rather than Web GUIs [48], as we believe GUIs are primarily user-friendly interfaces for humans and not essential for agents. The following web functions have been developed to help the agent complete users' instructions:

- **search_product_by_query.** This function takes a textual query as input and returns detailed information on the 10 most similar products based on the query. We facilitate this function using BM25 with Pyserini [22] to enable fast retrieval from a database of all products.
- get_recommendations_by_history. This function accepts a sequence of product IDs and returns 10 recommended products. To implement this, we trained the SASRec model [16] on our conducted benchmark, with cold-start products removed.
- **add_produc_review.** Designed to simplify the process of adding a product review, the only parameter this function requires is the review text. We assume the review is posted on the website once this function is successfully invoked.
- **respond.** This function allows the agent to engage in dialogue with the user, enabling clarification or gathering of additional information.
- **stop.** The stop function signals the termination of the current task. When invoked, it indicates that the agent decided to end the task, and no further actions are required.

3.3 Evaluation

To thoroughly evaluate the capabilities of Web agents, we established two distinct evaluation tracks: the single-turn track and the multi-turn track.

• **Single-turn track.** In this track, the agent is given only one opportunity to execute the user's instruction. The Web agent is expected to invoke the appropriate Web functions and deliver accurate results by configuring these functions with optimal parameters. Therefore, we define two metrics as follows:

465

466

467

468

469

470

471

472

473

474

475

476

items Train Test # Users 939 1.000 # Avg. profile tokens 247 User # Avg. behavior length 32 38 # Avg. behavior tokens 7,597 9,270 # Instructions 2.174 6,896 Instruction # Avg. tokens 45 46 # Products 8.236 Product # Avg. tokens 665

Table 2: Statistics of the PersonalWAB Benchmark.

• Function accuracy (function acc): This metric assesses the agent's ability to select the correct function and provide parameters in the correct format. If the agent selects the appropriate tool for the task and the input parameters are correctly formatted, it receives a score of 1 for that task; otherwise, the score is 0.

Result accuracy (res acc): For search and recommendation instructions, we leverage the rank r of the target product within the returned product list from the tool as the metric, formulated as:

Res Acc =
$$\begin{cases} 1 - \frac{r-1}{10}, & \text{if } r \le 10, \\ 0, & \text{if } r > 10. \end{cases} \text{ with } r \in \mathbb{N}^+ \tag{1}$$

For review instructions, we assess the similarity between the agent's generated review and the user's actual review. We employ the sentence-transformer [33] model to compute the cosine similarity, yielding a res acc between 0 and 1.

• Multi-turn track. We believe it is crucial for Web agents to interact with users to receive feedback and continuously adjust their actions. Since using real humans for benchmark evaluation is impractical, we conduct user simulators based on LLMs to give real-time feedback. Specifically, we provide the LLM with user profiles, target product information, or ground-truth reviews to facilitate high-quality interactions between user simulators and Web agents. Please refer to Figure 14 for the details of the user simulator prompt.

In addition to the two metrics used in the single-turn track, we introduce an additional evaluation metric: average steps. This metric measures efficiency by counting the total number of actions taken to complete the task, encouraging the agent to accomplish users' tasks with minimal attempts.

4 Benchmark Analysis

Statistic Analysis 4.1

We present the basic statistical information of our conducted PersonalWAB in Table 2. Since user profiles are generated in our benchmark, we analyze the diversity of all users and the consistency of 513 each user's profile, to verify the reliability of PersonalWAB.

• User statistics. In Figure 3, we present the basic attributes of 515 516 user profiles to illustrate the distribution. The data shows a reasonable spread across gender and age groups, while occupation 517 categories cover a wide range of fields, ensuring diverse profes-518 sional backgrounds in the dataset. The statistics in Figure 4 (a) 519 520 highlight additional diversity in behavioral attributes such as Price 521 Sensitivity, Diversity Preference, and Interaction Complexity. Most

Conference acronym 'XX, June 03-05, 2018, Woodstock, NY

Figure 3: Distribution of users by gender, age, and occupation.

Figure 4: (a) Distribution of behaviors by Price Sensitivity, Diversity Preference, and Interaction Complexity; (b) Statistics of the instructions on different tasks.

Figure 5: Results of profile consistency evaluation experiments. Our generated profiles align better with users' actual Web behaviors and interested products than Apollonion [3].

users fall into the "medium" category across these behavioral aspects, and the "high" and "low" categories are less frequent, which allows for testing both typical and edge cases in personalized tasks.

• Instruction statistics. We examined the number and average token length of different instructions in Figure 4 (b). It is observed that the recommendation instructions have the smallest number of tokens because the recommendation is an exploratory task and doesn't contain many user information requirements. The review instructions show slightly higher complexity compared to search and recommendation instructions, as they include many words for users to express their initial evaluations.

4.2 **Profile Consistency Evaluation**

Following [3], we conducted experiments on profile-behavior consistency and profile-product consistency to verify how well the generated profiles align with users' actual past Web behaviors and potentially interesting products. 1) Profile-behavior consistency evaluation. The task was to match a user profile with the user's past Web behaviors among those of other users. 2) Profile-product consistency evaluation. The task involved ranking a mixture of previously interacted (positive) and randomly sampled (negative) items for a user, based on their profile. The results in Figure 5 show that our constructed profiles provide substantial improvements in both profile-product and profile-behavior consistency evaluations

compared to Apollonion [3], showcasing the enhanced distinctiveness and alignment of the profiles with the actual user behaviors. More details are in § A.1.

To enable the Web agent to effectively complete tasks following user instructions, we propose a novel PUMA framework, which consists of two key steps: Web function identification and function parameter generation. First, we fine-tune an LLM (e.g., LLaMa-2-7b [42]) with "instruction-function" pairs in the training set to identify the correct Web functions given a user instruction. Then, we generate the appropriate parameters for the identified function. To achieve this, PUMA first adopts a memory bank to store the users' longterm Web behaviors and utilizes a task-specific retrieval strategy to obtain the most relevant ones from the memory bank. With the obtained user behaviors and features, we instruct the LLM to generate the corresponding parameters. However, generating the appropriate parameters for the identified function poses a significant challenge due to the vast parameter space. To address this challenge, PUMA applies heuristic methods to construct pseudo-labels to further finetune the LLM and optimize parameter generation using DPO [32], ensuring superior alignment with user preferences.

5.1 Task-specific Memory Retrieval

• Long-term memory bank. The long-term memory bank is a storage system where we maintain a detailed record of each user's historical Web behaviors. For a user u, we store detailed information about their purchased products $h_{purchase}$ and the associated reviews h_{review} , collectively denoted as m. Specifically, the product details include attributes such as "title", "price", "store", and other relevant metadata, while the review details encompass the "rating", "review title", and "comment" provided by the user. Formally, if the user u has purchased n products, the long-term memory M is represented as: $M = \{m_i \mid i = 1, 2, ..., n\}$.

616 • Task-specific memory retrieval strategy. The task-specific 617 memory retrieval strategy is designed to extract relevant informa-618 tion from the long-term memory bank based on the user's current 619 instruction and the identified function. When the user u provides 620 an instruction i and the Web function f is determined, we first 621 retrieve the top K memory entries by computing the cosine similar-622 ity between the instruction *i* and each memory m_i in the bank *M*. 623 Then, based on the specific function f, we extract more targeted 624 features from the retrieved memory. 1) If the Web function is re-625 lated to search, we extract product details including the "product 626 title", "category", "price", and "store". 2) If the function pertains to 627 the recommendation, we retain the product "title", "category", and 628 "parent ASIN" (product ID). 3) For review functions, only the user's 629 past ratings and comments are kept. This process can be formally 630 defined as:

$$M_i = \text{Extract} \left(\text{TopK} \left(M, \sin(i, m_i), K \right), f \right).$$
(2)

 M_i represents the task-specific memory constructed for instruction *i*. Extract(\cdot , f) represents extracting targeted features based on the identified Web function f. The similarity $sim(i, m_j)$ is the cosine similarity between the instruction i and memory entry m_j . 639

640

5.2 Function Parameter Optimization

Given the task-specific memory M_i , the next step involves utilizing this memory to generate the Web function parameters. We begin by using SFT to equip the model with a foundational ability to generate reasonable parameters.

• Heuristic fine-tuning for parameter generation. The inputs for SFT are structured as a combination of the user instruction *i*, the task-specific memory M_i , and the identified Web function *f*. The labels are the Web function parameters, constructed using heuristic methods tailored to each Web function. 1) For the search function, we leverage ChatGPT [29] to generate textual queries based on the instruction, and memory. 2) For recommendations, the output consists of the most recent product ASINs from the same category found in the memory M_i . 3) For review functions, we use the actual review text provided by the dataset as the labels. These heuristics help construct meaningful pseudo-labels for parameter generation, ensuring that the model learns to generate function parameters that are plausible and contextually appropriate for each Web function.

• Diverse parameter sampling for pair-wise optimization. After SFT equips the model with fundamental ability, we further enhance the model's performance through DPO [32] over diverse parameter candidates. We first generate a diverse set of function parameters with high-temperature sampling and beam search. These candidate parameters are then evaluated based on their result accuracy for instruction completion. For instruction *i*, we collect best-performing (p_i^b) and worst-performing (p_i^w) parameter pairs to construct the pair-wise preference data, which is formally defined as \mathcal{D}_{DPO} :

$$\mathcal{D}_{\text{DPO}} = \left\{ \left(p_i^{\text{b}}, p_i^{\text{w}}, x_i \right) \right\},\tag{3}$$

where x_i represents the input, which includes the user instruction *i*, task-specific memory M_i , and Web function *f*.

We then apply DPO to optimize the fine-tuned model π_{ref} by encouraging it to generate function parameters similar to p_i^{b} and discouraging it from generating function parameters similar to p_i^{w} . The DPO loss is given by:

$$\mathcal{L}_{\text{DPO}} = -\mathbb{E}\left[\log\sigma\left(\beta\log\frac{\pi_{\theta}(p^{\text{b}}\mid x)}{\pi_{\text{ref}}(p^{\text{b}}\mid x)} - \beta\log\frac{\pi_{\theta}(p^{\text{w}}\mid x)}{\pi_{\text{ref}}(p^{\text{w}}\mid x)}\right)\right],\tag{4}$$

where $\sigma(\cdot)$ is the sigmoid function, and β is a temperature-like parameter that controls the sensitivity of the model's preference to the log-ratio difference between the policy model π_{θ} for optimization and reference model π_{ref} derived from the SFT stage.

6 Experiments

We evaluate a range of baselines that employ different strategies for selecting and utilizing user history. These baselines are categorized into three groups: Memory Retrieval based Methods (No Memory, Random Memory, Last Memory, Relevant Memory), Enhanced Reasoning Methods (ReAct [51], Reflection [37]), and Recommendation-Specific Memory Frameworks (Recmind [44], InteRecAgent [14]). The implementation details of baselines and our method are illustrated in § A.2 and § A.3.

Table 3: Performance comparison between our proposed method, PUMA, and baselines in single-turn track. Bold numbers indicate the best performance in each column, while underlined numbers indicate the second-best performance.

Mathad (backbong)	Search		Recommendation		Review		Overall

6.1 Main Results

We evaluated baselines and our framework on both single-turn and multi-turn evaluation tracks.

6.1.1 Single-turn Track. The results on the single-turn track are shown in Table 3, highlighting several key insights: 1) It was observed that while search instructions had high function accuracy, the performance for recommendation instructions was poor. Further analysis revealed that many recommendation instructions were incorrectly assigned to the search function, as visualized in Figure 7 (b), indicating the great difficulty in function selection. 2) Methods incorporating relevant memory and ReAct show improved function accuracy, suggesting that retrieving relevant information and incorporating reasoning improve function selection. 3) The result accuracy for all baselines remains similar to the naive "No Memory' baseline, implying these methods fail to significantly enhance personalized task execution. 4) In contrast, PUMA achieves the highest function accuracy across tasks, with task-specific memory enabling the agent to focus on relevant behaviors and features, leading to higher result accuracy. Additionally, PUMA delivers the best overall performance while using shorter memory and a smaller LLM, highlighting the efficiency and effectiveness of our approach.

6.1.2 Multi-turn Track. The multi-turn track results (Table 4) of fer valuable insights into how different methods handle complex
 interactions. 1) First, baselines perform better in search and recommendation tasks compared to the single-turn track, benefiting from

multiple attempts and user feedback, while review tasks show minimal improvement, as the agents typically follow a straightforward flow with limited feedback opportunities. 2) The memory retrieval baselines follow similar trends to the single-turn track, with relevant memory improving function accuracy and result accuracy, but at the cost of additional steps. 3) ReAct and Reflection perform worse than memory retrieval methods, requiring more steps and yielding lower accuracy. The complexity of these methods, which include reasoning and self-reflection, seems to hinder task efficiency and accuracy with extra input token length. 4) RecMind also requires a higher number of steps, as it performs additional function calls, but struggles with instruction identification. InteRecAgent uses fewer steps due to its streamlined memory, but this simplification results in lower result accuracy. 5) Our Task-specific Memory method performs strongly, particularly in search and recommendation tasks. By effectively extracting relevant information and filtering out redundant data, it enables more informed decisions with fewer steps. Although we did not evaluate the full PUMA approach due to model limitations in multi-turn settings, the results highlight the importance of task-specific memory in enhancing both efficiency and accuracy.

6.2 In-depth Analysis

We performed a comprehensive analysis of PUMA on ablation study, memory length, efficiency, action transitions, and multi-turn performance variation. The results for the first two are provided in § A.4 due to the limited scope.

time (in seconds) for different methods.

6.2.1 Analysis on efficiency. In real-world applications, task completion time is crucial for delivering a smooth user experience. To evaluate it, we measured the time taken to complete the user instruction in the single-turn track. Each method was tested on 100 randomly selected tasks, and the average completion time was calculated. The results in Figure 6 show that GPT-based methods have similar completion times, ranging from 6.5 to 6.9 seconds, due to memory processing overhead. In contrast, our PUMA framework significantly outperforms all baselines, with an average time of 2.8 seconds. This efficiency gain stems from PUMA's smaller model and compact memory structure, minimizing inference time, making it highly effective for real-world Web applications where quick response times are essential.

838 6.2.2 Analysis on action transitions. We collected PUMA's actions 839 in each interaction turn within the multi-turn track. Review in-840 structions were removed, as the agent typically completes them 841 in just two steps. The results, visualized in Figure 7, provided the 842 following insights. 1) For search instructions, the agent tends to 843 alternately call "search" and "respond" functions. It is reasonable 844 as the agent could receive user feedback via the "respond" function 845 and thus adjust its search action. 2) The bond for the recommen-846 dation instructions is more entangled in Figure 7 (b), indicating a 847 more complex action transition. This underlines the challenge in 848 multi-turn recommendation tasks, where correctly identifying user 849 intent and dynamically adjusting actions are more difficult than in 850 straightforward tasks like search. 851

6.2.3 Analysis of multi-turn performance variation. We evaluated 852 the agent's performance over multiple attempts in the multi-turn 853 track. For each instruction, we measured the "Res Acc," and the 854 855 number of solved tasks as the number of attempt steps increased. The results are shown in Figure 8, and we had the following ob-856 857 servations. 1) The high task count within the first five attempts 858 indicates that most tasks are completed early on. The "review" task is typically finished within the first two attempts, as there's little 859 need for the agent to interact with users about the review require-860 ments. 2) "Res Acc" is high during the initial attempts and declines 861 with each subsequent attempt. This is because the easier tasks can 862 be solved in a few attempts, leaving the more difficult tasks for later. 863 3) There are a few outliers where tasks achieve higher "Res Acc" 864 in later steps. However, these cases are rare, involving only one 865 or two tasks that result in the outlier. 4) The declined "Res ACC" 866 also suggested that the agent struggles to leverage user feedback in 867 868 later attempts effectively. This may be due to the lack of multi-turn 869 training data, preventing us from tuning the agent accordingly.

Figure 8: Analysis of the agent's performance across multiple attempts in multi-turn track.

7 Conclusion and Future Work

In this paper, we advanced general LLM-based Web agents into the era of personalized Web agents, aiming to offer users tailored and customized services. We formulated the task of LLM-empowered personalized Web agents and identified the goal of leveraging personalized user data to achieve personalized instruction understanding and action execution (Web function call). For training and evaluation, we constructed the first PersonalWAB benchmark on three personalized Web tasks. We proposed PUMA, a novel personalized alignment framework with task-specific memory and function parameter optimization strategies, to adapt LLMs to personalized Web agents. Extensive experiments on PersonalWAB demonstrate that PUMA consistently surpasses existing Web agents, aligning better with personalized user instructions and preferences. We believe that the task, benchmark, and framework for LLM-empowered personalized Web agents will broaden the research scope, introduce new challenges, and inspire novel methods in Web agent scenarios.

While our research lays the groundwork for personalized Web agents, several avenues for future exploration remain. First, we plan to extend PersonalWAB by incorporating more diverse task scenarios to further challenge and evaluate Web agents' personalization capabilities. Second, integrating more sophisticated user modeling techniques, such as dynamic preference learning, could enhance agents' adaptability to evolving user needs. Third, exploring user-in-the-loop settings presents an exciting opportunity to improve task execution by actively involving users in the process. This includes developing agents that can better integrate user feedback, proactively identify missing information, and engage with users to request necessary details, thereby enhancing the overall effectiveness and efficiency of task completion.

A.1 Details of Profile Evaluation Experiments

Profile-behavior consistency evaluation. Given a specific user profile, the task is to identify the correct user from a group of candidate users, consisting of the true user and several negative users. Each candidate user is represented by their behavior sequence, and the objective is to determine which candidate aligns best with the given profile. The evaluation metric used is top-1 accuracy, indicating the ability of the profile to distinctly and accurately match the correct user based on their behaviors.

Profile-product consistency evaluation. In this task, a given
user profile is used to rank a set of candidate items, which include
a mixture of positive items (previously interacted with by the user)
and negative items (randomly sampled from an item pool). The
objective is to prioritize positive items over negative items, leveraging the user profile for accurate ranking. The task is evaluated

with NDCG@5 and Recall@5, which measure the profile's ability to reflect the user's preferences.

We adopt the same setting with [3], set the number of positive samples to 1 and 3, and negative samples to 4 and 7 in the user prediction and recommendation tasks, respectively. Experiments are conducted with gpt-4o-mini-2024-07-18, and results in Figure 5 show our profile exhibits significant improvements across both tasks, indicating that our profiles are more distinct and better aligned with user behaviors.

A.2 Details of Baselines

We evaluate a range of baselines that employ different strategies for selecting and utilizing user Web behavioral history. These baselines are categorized into three groups: Memory Retrieval Methods, Enhanced Reasoning Methods, and Recommendation-Specific Memory Frameworks.

Memory Retrieval Methods. We include various simple memory mechanisms as baselines, aiming to explore different strategies for selecting and utilizing user history. This helps us understand how each memory selection technique impacts task performance. 1) No Memory: The agent performs tasks without accessing any user history, relying solely on the current instruction. 2) Random Memory: This approach randomly selects behaviors from the user's history. 3) Last Memory: Uses only the most recent behaviors from the user's history, focusing on the assumption that recent context is more relevant for current instruction. 4) Relevant Memory: Selects past behaviors based on cosine similarity with the current instruction, aiming to filter out the most contextually relevant details for the task.

Enhanced Reasoning Methods. We also tested frameworks designed to enhance the agent's reasoning and decision-making capabilities. 1) ReAct: Proposed by [51], this framework instructs the language model to think before taking an action and generate "Thought: some reasoning Action: some JSON format action argument" to interact, enabling the model to deliberate over the information available and decide on the most appropriate action. 2) Reflection: Reflection [37] builds on frameworks of ReAct by adding a self-evaluation phase, where the agent reviews and analyzes its previous actions and outcomes before proceeding. This process allows the agent to recognize mistakes, reassess decisions, and refine its strategy in subsequent interactions. We tested this baseline only in the multi-turn track, where the agent treats each user message as feedback for reflection and adjustment.

Recommendation-Specific Memory Frameworks. Recommendation tasks are inherently personalized, as they rely on a deep understanding of user preferences and behaviors. Given this, we include baselines that leverage memory mechanisms developed for recommendation agents, assessing their ability to enhance personalization in our context. 1) RecMind: An LLM-powered agent designed for general recommendation purposes [44], consists of two parts of memory, personalized memory, and world knowledge. Personalized Memory includes individualized user information, such as their reviews or ratings for a particular item. World Knowledge consists of item metadata information and real-time information accessed with a Web search function. In our setup, we retain the personalized memory containing user reviews and ratings, and we 1115

incorporate an additional function to enable RecMind to access de-1178 tailed product information. 2) InteRecAgent: Proposed by [14], this 1179 framework uses LLMs as the core reasoning engine while utilizing 1180 recommender models as functions for interactive recommendations. 1181 Its memory structure includes a candidate bus (which stores current 1182 item candidates) and a user profile that captures three facets of user 1183 preferences: "like", "dislike", and "expect". We adopt the user profile 1184 memory in our experiments and allow the agent to update this 1185 profile at the end of each task. As the user profile is synthesized 1186 by LLMs based on conversation history with the user, we evaluate 1187 this method only in the multi-turn setting, where ongoing dialogue 1188 allows for continuous adaptation of the user profile. 1189

A.3 Implementation Details

Benchmark. We utilize gpt-4o-mini-2024-07-18 for generating user profiles, as it excels at extracting detailed user preferences, particularly in capturing brand preferences. For user instruction creation, we employ claude-3-5-sonnet@20240620, selected for its ability to produce instructions in a natural and human-like tone. In multi-turn track, gpt-4o-mini-2024-07-18 is also used to simulate user messages, as it follows the instructions better to give user messages.

Baselines. We use gpt-4o-mini-2024-07-18 as the base lan-1202 guage model across all baseline methods. For memory retrieval 1203 baselines, we set the memory length to 50 behaviors for the single-1204 1205 turn track and 20 behaviors for the multi-turn track, allowing additional input length for user messages and function results. For 1206 the Relevant Memory method, we calculate cosine similarity us-1207 1208 ing the sentence-transformer [33] to identify relevant behaviors. 1209 The ReAct baseline is combined with the Last Memory approach to ensure that reasoning processes have recent context, and we 1210 further extend this with a Reflection mechanism for multi-turn 1211 1212 scenarios. For RecMind, the memory length is set to 400 behaviors, as it only contains user reviews and ratings, and we added an extra 1213 "get_product_details_by_asin" function for the agent to retrieve 1214 detailed product information. In the InteRecAgent setup, we first 1215 construct the memory using historical behaviors and the training 1216 dataset before evaluating performance on the test set. 1217

PUMA. We collect the search function parameters of gpt-4o-mini (2024-07-18) as the initial SFT data. In the function parameter optimization phase, we fine-tune the LLaMA2-7B [42] model with LoRA [13] using 4 × 24GB NVIDIA A5000 GPUs. The learning rate is set to 4e-3 for the SFT and 5e-5 during the DPO stage, with a batch size of 1 per GPU. Due to the maximum sequence length we can afford during training is limited, we constrain the memory token length to 256, 512, and 768 tokens. To generate diverse function parameters, we set a temperature of 1.5 to increase output variability and use a beam search with a beam size of 10.

A.4 More Analysis

Ablation study. We conducted an ablation study (Table 5) to assess the impact of PUMA's key components. First, removing the memory leads to a significant drop in result accuracy across all tasks, highlighting the importance of memory in retaining relevant information for function parameter generation. Second, when memory is retained but the SFT phase is removed, result accuracy dramatically declines. This indicates that without fine-tuning, the model struggles to generate function parameters that align with user needs. Finally, removing the DPO phase results in a slight performance decrease, suggesting that DPO plays a crucial role in aligning the model with user preferences, and improving the quality of function parameters.

Analysis on memory length. We evaluated the impact of different memory token lengths on our framework's performance across tasks. The experiment measured both function accuracy and result accuracy with varying memory sizes. The results (Table 6) indicate that increasing memory length has minimal impact on function accuracy, with the model maintaining similar performance regardless of memory size. However, memory length has a significant effect on result accuracy, particularly in recommendation tasks. Shorter memory lengths reduce the number of stored products, limiting the model's ability to select appropriate product IDs, which leads to a noticeable drop in recommendation accuracy. In contrast, search and review tasks are less sensitive to memory length changes, as the agent relies more on information from the instruction rather than the memory. This reduced dependence on memory in these

User Profile Generation	
You will act as an online shopper.	
Given your time-series historical purchase information and corresponding reviews, you need to summarize and choose the	most
accurate and relevant option best describing you.	
During summarizing you should obey the following procedures:	
First, summarize your basic information, and choose or fill the most accurate and relevant option for each category.	
The categories and options are as follows:	
• Gender: <gender>.</gender>	
• Age: <age>.</age>	
• Occupation: <occupation>.</occupation>	
Price Sensitivity: <price sensitivity="">.</price>	
Shopping Interest: Summarize the product information.	
Brand Preference: Choose from the product information, and only keep brand names.	
Second, summarize your personal preferences across the following aspects:	
Diversity Preference:	
Do you prefer trying new things or sticking to familiar products? Choose from <diversity>.</diversity>	
• Interaction Complexity	
Do you prefer simple and concise interactions, or do you enjoy detailed and thorough exchanges? Choose from <interacti • Tone and Style</interacti 	DN>.
Summarize your overall emotional tone, speaking style, and expressive characteristics when giving reviews. Keep keywords. • Item Reference	
Summarize your tendency to refer to specific products or brands in your reviews, like purchase history, shopping cart, or recon	men
dations from friends. Keep keywords.	
• Focus Aspect	
What aspects of products do you pay more attention to? Choose from <focus aspect=""> or summarize others from reviews. keywords.</focus>	Кеер
n the end, arrange all the above aspects using the JSON format, with each aspect as an individual key.	
Do not include any additional information or explanations and stay grounded.	
/our History:

Review Instruction Generation You will act as an online shopper. Your Profile: <PROFILE>, You have recently purchased the following product: <PRODUCT>, Your feelings about the product are: <REVIEW>, Now, You want to write a review. Generate a review request to ask for assistance to create a complete review that reflects your preferences and typical review style. Rules: • <INTERACTION>. • You value <FOCUS_ASPECT> of products, but keep the request open-ended to allow for a variety of recommendations. Ensure the review request aligns with your overall tone and style: <TONE_AND_STYLE>. • Do not simply restate your profile or feedback verbatim. Instead, paraphrase and expand to reflect a more comprehensive review. • Try to make the request as natural as possible and stick to the personalities in your profile. • Do not include any additional information or explanations and stay grounded. • Do not hallucinate information that is not provided. • No more than <NUM> words. Figure 13: Review instruction generation. **User Simulation Instruction** You are a user interacting with a personalized shopping agent. Your Profile: <PROFILE> You have purchased the following product: <PRODUCT> (In review tasks:) Your review is as follows: <REVIEW> The shopping agent will help you complete your shopping requests. Rules: • Just generate one line at a time to simulate the user's message. • Do not hallucinate information that is not provided. • Do not give additional instructions or ask questions, only respond to the agent's questions. • Do not provide any specific product details. • Do not repeat the exact information in your profile or product. Instead, use your own words to convey the same information. • Try to make the conversation as natural as possible and stick to the personalities in your profile. • If the result is not satisfactory, you can express your dissatisfaction and provide clues to help the agent understand your preferences.
