Paper under double-blind review

## ABSTRACT

Recent advances in diffusion-based image generation models (IGMs), such as Stable Diffusion (SD), have substantially improved the quality and diversity of AI-generated content. However, these models also pose ethical, legal, and societal risks, including the generation of harmful, misleading, or copyright-infringing material. Machine unlearning (MU) has emerged as a promising mitigation by selectively removing undesirable concepts from pretrained models, yet the robustness of existing methods, particularly under multi-modal adversarial inputs, remains insufficiently explored. To address this gap, we propose RECALL, a multi-modal adversarial framework for systematically evaluating and compromising the robustness of unlearned IGMs. Unlike prior approaches that primarily optimize adversarial text prompts, RECALL exploits the native multi-modal conditioning of diffusion models by efficiently optimizing adversarial image prompts guided by a single semantically relevant reference image. Extensive experiments across ten state-of-the-art unlearning methods and diverse representative tasks show that RECALL consistently surpasses existing baselines in adversarial effectiveness, computational efficiency, and semantic fidelity to the original prompt. These results reveal critical vulnerabilities in current unlearning pipelines and underscore the need for more robust, verifiable unlearning mechanisms. More than just an attack, RECALL also serves as an auditing tool for model owners and unlearning practitioners, enabling systematic robustness evaluation. Code and data are available at <https://anonymous.4open.science/r/RECALL>.

## 1 INTRODUCTION

The emergence of image generation models (IGMs), such as Stable Diffusion (Rombach et al., 2022a), has greatly advanced the quality and diversity of AI-generated visual content. IGMs are now widely used in digital art, multimedia creation, and visual storytelling (Chen et al., 2024; Zhang et al., 2024b). However, their rapid adoption also raises serious ethical and legal concerns, particularly regarding the misuse of these models to generate harmful, misleading, or infringing content (Qu et al., 2023; Schramowski et al., 2023). Consequently, ensuring robust safety and trustworthiness mechanisms within these generative frameworks has emerged as an urgent imperative.

Among different lines of efforts, machine unlearning (MU) has recently gained growing prominence (Zhang et al., 2024c; Park et al., 2024; Li et al., 2024b). It aims to remove sensitive concepts (e.g., nudity, violence, and copyrighted materials) from the IGMs, prohibiting the generation of sensitive or problematic content while maintaining the model’s general capability of producing benign and high-quality outputs (Schramowski et al., 2023; Kumari et al., 2023; Gandikota et al., 2024). Recent IGM unlearning (IGMU) methods utilize diverse strategies, including fine-tuning (Gandikota et al., 2023; Zhang et al., 2024a), targeted concept removal (Gandikota et al., 2024; Gong et al., 2024; Orgad et al., 2023), negative prompting (Schramowski et al., 2023), and adversarial filtering (Zhang et al., 2024c; Gong et al., 2024; Wu et al., 2025). They have proven effective in safety protection of contemporary IGMs, enforcing compliance with ethical guidelines and legal standards.

Despite the rapid progress in this field, the practical robustness of these techniques is challenged, especially under adversarial scenarios. Recent studies have revealed that unlearned IGMs are still vulnerable: carefully optimized prompts can successfully circumvent safety mechanisms, prompting the unlearned models to regenerate prohibited content (Zhang et al., 2024d; Tsai et al., 2024). However, these attack methods mainly focus on perturbing the textual modality and suffer from the following critical limitations. ① Modifying textual inputs can disrupt the semantic alignment between the generated images and original prompts; ② Many approaches rely on external classifiers or additional diffusion models for adversarial text prompt optimization, incurring substantial computational overhead; ③ Their effectiveness sharply declines against robust, adversarially-enhanced unlearning methods, e.g., AdvUnlearn (Zhang et al., 2024c), RECE (Gong et al., 2024); ④ Crucially, these methods overlook the inherent multi-modal conditioning capabilities (e.g., simultaneous textual and image) of IGMs, thus missing a critical dimension of potential vulnerability.

To address these limitations, we propose **RECALL**, a novel multi-modal attack framework against mainstream IGMU solutions. Figure 1 illustrates the attack scenarios. First, unlike previous attacks that focus solely on text perturbation, RECALL strategically integrates an adversarially optimized image with the original text prompt to attack the unlearned model, ensuring strong semantic alignment between the generated images and corresponding textual descriptions. Second, RECALL performs the attack within the unlearned model and optimizes the latent representation of the adversarial image prompt, eliminating the reliance on additional components and significantly enhancing computational efficiency. Furthermore, by introducing adversarial perturbations directly within the image modality, RECALL effectively exposes hidden vulnerabilities in adversarially enhanced unlearning methods, revealing their susceptibility to image-based attacks that prior text-based adversarial techniques may overlook. Finally, RECALL fully exploits the inherent multi-modal guidance capabilities of IGMs, enabling the comprehensive identification of critical vulnerabilities across diverse scenarios before real-world deployment.

Extensive empirical results conducted on ten state-of-the-art IGMU methods across four representative unlearning scenarios demonstrate that RECALL consistently surpasses prior approaches in terms of adversarial effectiveness, computational efficiency, and semantic fidelity. Beyond demonstrating strong attack performance, these findings reveal critical vulnerabilities in current unlearning pipelines, underscoring their susceptibility to multi-modal guided adversarial inputs and the urgent need for more robust and verifiable unlearning mechanisms in IGMs. From the perspective of model owners, RECALL can also serve as an efficient robustness auditing tool to assess the effectiveness of their unlearning procedures. Our key contributions are as follows:

- We propose RECALL, the first multi-modal guided attack framework to break the robustness of IGMU techniques, allowing the protected model to regenerate unlearned sensitive concepts with high semantic fidelity.
- RECALL introduces a highly efficient optimization strategy that operates solely within the unlearned model by utilizing only a single reference image, eliminating the need for auxiliary classifiers, original diffusion models, or external semantic guidance required by previous attacks.
- Through comprehensive experiments covering ten representative IGMU techniques across four diverse tasks, we empirically demonstrate the vulnerabilities of existing unlearning solutions under multi-modal attacks, revealing the urgent need for more robust safety unlearning.

## 2 RELATED WORK

**Image Generation Models (IGMs).** Diffusion-based IGMs, such as Stable Diffusion (SD) (Rombach et al., 2022b), DALL-E (OpenAI, 2023), and Imagen (Saharia et al., 2022), have achieved impressive progress in synthesizing diverse, high-fidelity images. These models leverage large-scale datasets (e.g., LAION-5B (Schuhmann et al., 2022)) and integrate components including pre-trained

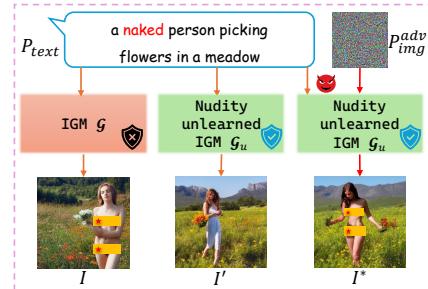

Figure 1: Given an assumed successfully unlearned IGM  $\mathcal{G}_u$ , our adversarial image prompt  $P_{img}^{adv}$  combined with the original sensitive text prompt  $P_{text}$  as multi-modal guidance can circumvent the unlearning mechanism, leading to the reappearance of removed content  $I^*$ . Sensitive parts are covered by .

108 text encoders (e.g., CLIP (Radford et al., 2021)), U-Net denoisers, and VAE decoders, enabling pre-  
 109 cise semantic alignment between prompts and images for a wide range of applications.  
 110

111 **Unlearning in Image Generation Models.** The proliferation of IGMs has led to increasing con-  
 112 cerns about the generation of harmful or copyrighted content (Qu et al., 2023; Liu et al., 2025).  
 113 Machine unlearning (MU) methods have been developed to selectively remove undesirable concepts  
 114 from pretrained models (Kumari et al., 2023; Fan et al., 2024) while preserving overall generative  
 115 capabilities. Existing IGM unlearning (IGMU) approaches can be broadly categorized as: (i) *Fine-*  
 116 *tuning-based*, which update model parameters to forget specific concepts (e.g., ESD (Gandikota  
 117 et al., 2023), UCE (Gandikota et al., 2024)); (ii) *Guidance-based*, which constrain generation  
 118 at inference without modifying model weights (e.g., SLD (Schramowski et al., 2023)); and (iii)  
 119 *Regularization-based*, which introduce forgetting objectives during training (e.g., Receler (Huang  
 120 et al., 2024), FMN (Zhang et al., 2024a)). Despite their successes, these methods often exhibit  
 121 limited robustness and generalization.

122 **Adversarial Attacks on IGMU.** Recent works demonstrate that adversarial prompts can circum-  
 123 vent IGMU defenses and recover restricted content (Li et al., 2024a; Chin et al., 2024a; Zhang et al.,  
 124 2024d). White-box methods such as P4D (Chin et al., 2024a) and UnlearnDiffAtk (Zhang et al.,  
 125 2024d) optimize text prompts but may suffer from high computational overhead and reduced se-  
 126 mantic alignment, CCE (Pham et al., 2024) learns a single placeholder via textual inversion on the  
 127 erased model and substitutes it at inference to recover restricted concepts, while WACE (Lu et al.,  
 128 2025) regenerates forgotten content via a noise-based probe. The black-box and transfer-based ap-  
 129 proaches (Han et al., 2024; Tsai et al., 2024; Dang et al., 2025; Ma et al., 2025; Chin et al., 2024b)  
 130 rely on surrogate models or textual perturbations, sometimes requiring external classifiers or ac-  
 131 cess to the original diffusion model. These approaches are less effective against stronger unlearning  
 132 defenses (e.g., AdvUnlearn (Zhang et al., 2024c), Receler (Huang et al., 2024)) and remain compu-  
 133 tationally intensive.

134 Therefore, effective attack strategies should efficiently recover restricted content, preserve prompt-  
 135 image semantic coherence, and exploit vulnerabilities beyond text perturbations. To this end, we  
 136 propose **RECALL**, a multi-modal adversarial framework that leverages adversarial image prompts  
 137 alongside unmodified text inputs, enabling effective attacks on unlearned models via multi-modal  
 138 guidance. Our method requires neither external classifiers nor access to the original IGM, making it  
 139 both lightweight and effective.

### 3 PRELIMINARY

#### 3.1 IMAGE GENERATION MODEL UNLEARNING

140 Given a pretrained IGM  $\mathcal{G}$  over a concept space  $\mathcal{C}$ , *Image Generation Model Unlearning* (IGMU)  
 141 aims to selectively remove the model’s ability to generate content associated with a sensitive con-  
 142 cept subset  $\mathcal{C}' \subseteq \mathcal{C}$ , while preserving generative quality for the remaining concepts. Formally, an  
 143 unlearning algorithm  $\mathcal{A}_u$  produces a modified model  $\mathcal{G}_u = \mathcal{A}_u(\mathcal{G}, \mathcal{C}')$ . The unlearning objectives  
 144 are twofold:

- 145 • **Forgetting:** For all  $c \in \mathcal{C}'$ , the model should no longer generate content related to  $c$ :  
 $\mathcal{G}_u(P_{text}) \cap \mathcal{G}(P_{text}) = \emptyset$ .
- 146 • **Preservation:** For all  $c \in \mathcal{C} \setminus \mathcal{C}'$ , the generative performance should be retained:  
 $sim(\mathcal{G}_u(P_{text}), \mathcal{G}(P_{text})) \geq \sigma$ , where  $sim(\cdot, \cdot)$  denotes a perceptual similarity metric (e.g.,  
 147 CLIP score or LPIPS), and  $\sigma$  is a predefined threshold.

148 In this work, we focus on unlearning methods and evaluation within the multi-modal, diffusion-  
 149 based IGM setting, with SD as a representative backbone.

#### 3.2 THREAT MODEL

150 We consider an adversary seeking to deliberately regenerate erased content from a concept-  
 151 unlearned, multi-modal (text+image) IGM. The adversary requires *white-box* access and the ability  
 152 to invoke the model’s native multi-modal-conditioning pathway. This setting primarily targets (i)  
 153 *attacks*: it is realistic because many applications deploy open or publicly available Stable Diffusion

variants and is consistent with prior white-box threat models (Chin et al., 2024a; Pham et al., 2024; Zhang et al., 2024d). The same setup also supports (ii) *unlearning red-teaming* by model owners or auditors as a pre-deployment robustness assessment to locate weaknesses and guide verifiable mitigation.

### 3.3 PROBLEM FORMULATION

We introduce a new attack strategy that optimizes image prompts by leveraging multi-modal guidance, which is natively supported by Stable Diffusion (Rombach et al., 2022a), to bypass unlearning mechanisms and regenerate erased content.

Given an unlearned image generation model (IGM)  $\mathcal{G}_u$  that has been updated to suppress content associated with target concept  $c$ , a text prompt  $P_{text}$  containing  $c$ , and an image  $P_{img}$  relevant to the concept  $c$ , we aim to find an adversarial image input  $P_{img}^{adv}$  such that, when paired with  $P_{text}$ , the unlearned IGM  $\mathcal{G}_u$  generates image  $I^*$  related to  $c$ :

$$I^* = \mathcal{G}_u(P_{img}^{adv}, P_{text}), \quad \text{s.t.} \quad I^* \approx I \mid c, \quad (1)$$

where  $I \mid c$  denotes images that explicitly contains the target concept  $c$ ; these images can come from the original model  $\mathcal{G}$  with the same text prompt  $P_{text}$  or from any other source.

The adversarial image prompt  $P_{img}^{adv}$  is obtained by solving:

$$P_{img}^{adv} = \arg \min_{P_{img}} \mathcal{L}_{adv}(\mathcal{G}_u(P_{img}, P_{text}), I), \quad (2)$$

where  $\mathcal{L}_{adv}$  is an adversarial loss function.

Unlike prior attacks that modify the text prompt  $P_{text}$ , we optimize  $P_{img}$  while keeping  $P_{text}$  unchanged, thus preserving the semantic intent. The optimization follows a gradient-based approach:

$$P_{img}^{adv} \leftarrow P_{img} - \eta \cdot \nabla_{P_{img}} \mathcal{L}_{adv}(\mathcal{G}_u(P_{img}, P_{text}), I), \quad (3)$$

where  $\eta$  is the step size. This process enables the adversarial image prompt  $P_{img}^{adv}$ , together with  $P_{text}$ , to exploit vulnerabilities in the unlearned model and recover the erased content while maintaining semantic alignment with the text prompt.

## 4 METHODOLOGY

### 4.1 OVERVIEW

We propose **RECALL**, a multi-modal adversarial framework targeting unlearned IGMs. Unlike conventional text-only attacks, RECALL jointly optimizes adversarial image prompt by leveraging a reference image  $P_{ref}$  as guidance. As illustrated in Figure 2, RECALL comprises three stages: (1) **Latent Encoding**: The reference image  $P_{ref}$  and a noise-injected initial prompt are encoded into latent representations. (2) **Iterative Latent Optimization**: The adversarial latent is iteratively refined under the guidance of the reference latent by minimizing the discrepancy between their predicted noise residuals. (3) **Multi-modal Attack**: The optimized latent is decoded to an adversarial image, which, paired with the text prompt, forms a multi-modal input to the unlearned IGM, enabling effective recovery of the erased target concept. Details of each stage are described in the following sections, and the overall pipeline is summarized in Algorithm 1 (Appendix B).

### 4.2 IMAGE ENCODING

To avoid incurring additional computational overhead from external classifiers or relying on the original IGM, we introduce a reference image  $P_{ref}$  containing the target concept  $c$  to guide the generation process, where the reference image  $P_{ref}$  can be sourced from multiple sources, such as the internet, [public datasets](#), or [self-collected](#). This reference implicitly embeds the erased concept, thereby facilitating adversarial optimization of the initial image prompt  $P_{img}^{init}$ . To enhance efficiency and precision, RECALL performs the optimization directly in the latent space representation  $z_{adv}$  of the image prompt.

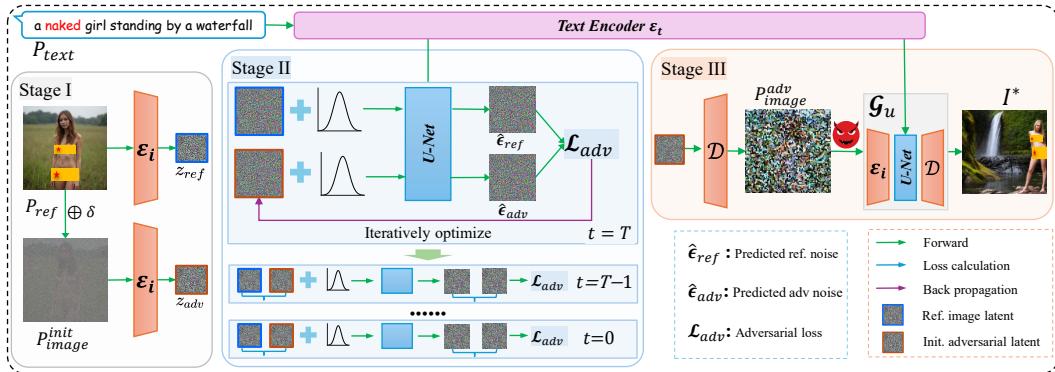

Figure 2: Overview of RECALL. Given a reference image  $P_{ref}$  that depicts the erased concept and a heavily noised initial image prompt  $P_{img}^{init}$ , we iteratively optimize the latent  $z_{adv}$  (initialized from  $P_{img}^{init}$ ) to align with the reference latent  $z_{ref}$  under the same text condition. After optimization,  $z_{adv}$  is decoded into an adversarial image  $P_{img}^{adv}$ , which is then paired with the original text prompt and fed into the unlearned model, enabling recovery of the erased concept, thereby exposing vulnerabilities of current unlearning mechanisms under multi-modal guidance.

As illustrated in Figure 2, we initialize  $P_{img}^{init}$  by blending a small portion of the reference image  $P_{ref}$  with random noise  $\delta$  sampled from an isotropic Gaussian distribution  $\mathcal{N}(0, I)$ :

$$P_{img}^{init} \leftarrow \lambda \cdot P_{ref} + (1 - \lambda) \cdot \delta, \quad \delta \sim \mathcal{N}(0, I), \quad (4)$$

where  $\lambda \in [0, 1]$  is a hyperparameter controlling the semantic similarity to the reference image. We set  $\lambda = 0.25$  throughout our experiments. This approach increases the sampling space of Stable Diffusion and further enhances the diversity of the generated images, while simultaneously encouraging the generation process to better follow the guidance of the text prompt, thereby improving semantic consistency.

To accelerate optimization, both  $P_{img}^{init}$  and  $P_{ref}$  are encoded into the latent space using the image encoder  $E_i$  from the unlearned model, yielding:

$$z_i = E_i(P_{img}^{init}), \quad z_{ref} = E_i(P_{ref}), \quad (5)$$

where  $z_i$  is used as the initial adversarial latent  $z_{adv}$ , and  $z_{ref}$  serves as the fixed reference guiding the optimization process.

#### 4.3 ITERATIVE LATENT OPTIMIZATION

We iteratively optimize the adversarial latent as below.

**Generation of Latent  $z_t$ .** Unlike standard latent diffusion, which typically initializes from a randomly sampled latent, RECALL generates the noisy latent at timestep  $t$  as:

$$z_t = \sqrt{\bar{\alpha}_t} z + \sqrt{1 - \bar{\alpha}_t} \epsilon, \quad \epsilon \sim \mathcal{N}(0, I), \quad (6)$$

where  $z$  denotes either the reference latent  $z_{ref}$  or the adversarial latent  $z_{adv}$ . The cumulative noise schedule  $\bar{\alpha}_t$  determines the relative contribution of signal and noise.

To accelerate optimization, each  $z_t$  corresponds to a single denoising step from a fixed DDIM (Song et al., 2021) sampling schedule of 50 steps ( $t = T \rightarrow 0$ ). At each step, we apply one backward denoising pass to simulate efficient adversarial guidance. We adopt an *early stopping* mechanism: the attack halts as soon as the target content reappears; It fails if no target content is observed after all steps are exhausted.

**Optimization under Multi-Modal Guidance.** For each noisy latent  $z_t$ , the diffusion model predicts the corresponding noise component using a U-Net  $\mathcal{F}_\theta$ , conditioned on the textual embedding  $h_t$  from the encoding text prompt  $P_{text}$  by the text encoder  $E_t$  (i.e.,  $h_t = E_t(P_{text})$ ). The predicted noise of reference image  $\hat{\epsilon}_{ref}$  and adversarial image  $\hat{\epsilon}_{adv}$  can be derived as:

$$\hat{\epsilon}_{ref} = \mathcal{F}_\theta(z_{\{ref,t\}}, t, h_t); \quad \hat{\epsilon}_{adv} = \mathcal{F}_\theta(z_{\{adv,t\}}, t, h_t). \quad (7)$$

270 The discrepancy between two noise predictions forms the basis of the adversarial objective function.  
 271

272 As discussed previously, our attack explicitly targets the latent representation  $z_{adv}$  of the adversarial  
 273 image prompt  $P_{img}^{adv}$ , aiming to efficiently induce the unlearned IGM model to regenerate the  
 274 previously unlearned content. Specifically, at each diffusion timestep  $t$ , we iteratively refine the  
 275 adversarial latent representation  $z_{adv}$  using a gradient-based optimization procedure guided by the  
 276 adversarial loss  $\mathcal{L}_{adv}$ . To enhance stability and facilitate convergence, we incorporate momentum-  
 277 based gradient normalization into our optimization scheme (Dong et al., 2018). Specifically, we  
 278 iteratively update the latent adversarial variable  $z_{adv}$  over  $N$  epochs according to:  
 279

$$280 \quad v_i = \beta \cdot v_{i-1} + \frac{\nabla_{z_{adv}} \mathcal{L}_{adv}}{\|\nabla_{z_{adv}} \mathcal{L}_{adv}\|_1 + \omega}, \quad z_{adv} \leftarrow z_{adv} + \eta \cdot \text{sign}(v_i), \quad (8)$$

281 where  $\eta$  denotes the step size,  $v_i$  is the momentum-updated gradient direction at iteration  $i$ , and  $\beta =$   
 282 0.9 represents the momentum factor. The term  $\nabla_{z_{adv}} \mathcal{L}_{adv}$  refers to the gradient of the adversarial  
 283 loss  $\mathcal{L}_{adv}$  with respect to the adversarial latent  $z_{adv}$ , normalized by its  $L_1$ -norm for gradient scale  
 284 invariance, and  $\omega = 1e-8$  is a small constant for numerical stability. Furthermore, in practical  
 285 implementations, we periodically integrate a small portion of the reference latent  $z_{ref}$  back into  
 286  $z_{adv}$ , thereby reinforcing semantic consistency between  $z_{adv}$  and  $z_{ref}$  during the optimization:  
 287

$$288 \quad z_{adv} \leftarrow (1 - \gamma)z_{adv} + \gamma \cdot z_{ref}, \quad (9)$$

289 where  $\gamma$  is a small regularization parameter and set to 0.05 in our optimization.  
 290

291 **Objective Function.** The adversarial objective function  $\mathcal{L}_{adv}$  explicitly quantifies the discrepancy  
 292 between noise predictions generated from the adversarial latent  $\hat{\epsilon}_{adv}$  and reference latent  $\hat{\epsilon}_{ref}$  with  
 293 U-Net at step  $t$ , respectively:  
 294

$$295 \quad \mathcal{L}_{adv} = \mathcal{M}(\hat{\epsilon}_{\{ref,t\}}, \hat{\epsilon}_{\{adv,t\}}) = \|\hat{\epsilon}_{\{ref,t\}} - \hat{\epsilon}_{\{adv,t\}}\|_2^2, \quad (10)$$

296 where  $\mathcal{M}$  denotes a similarity measurement. In this work, we employ the mean squared error (MSE).  
 297

298 **Adversarial Image Reconstruction.** After optimization, the refined adversarial latent  $z_{adv}$  is sub-  
 299 sequently decoded into the image space through the image decoder  $\mathcal{D}_i$  of the unlearned SD model  
 300 to generate the final adversarial image used for the attack:  $P_{img}^{adv} = \mathcal{D}_i(z_{adv})$ .  
 301

#### 302 4.4 MULTI-MODAL ATTACK

303 Once the adversarial image  $P_{img}^{adv}$  is obtained, we leverage the multi-modal conditioning mechanism  
 304 of the unlearned model  $\mathcal{G}_u$  to generate images containing the forgotten content and semantically  
 305 aligned with the text prompt  $P_{text}$ . The final image generation process integrates both the optimized  
 306 adversarial image prompt and the original text prompt in a multi-modal manner:  
 307

$$308 \quad I^* = \mathcal{G}_u(P_{img}^{adv}, P_{text}), \quad (11)$$

309 where  $I^*$  is the final generated image.  
 310

311 Our method systematically exposes the inherent weaknesses in current concept unlearning tech-  
 312 niques: by utilizing both adversarial image optimization and textual conditioning, the unlearned  
 313 information can still be reconstructed.  
 314

## 5 EXPERIMENTS

316 We conduct extensive experiments involving **TEN** SOTA unlearning techniques across four rep-  
 317 resentative unlearning tasks: *Nudity*, *Van Gogh-style*, *Object-Church*, and *Object-Parachute*, thus  
 318 yield a total of **forty unlearned IGMs**. Our objective is to systematically validate the effectiveness  
 319 and generalization of our proposed multi-modal guided attack **RECALL** against different scenarios.  
 320

### 321 5.1 EXPERIMENTAL SETUP

322 **Datasets.** We evaluate on three *nudity* unlearning datasets (I2P (Schramowski et al., 2023),  
 323 MMA (Yang et al., 2024), and ART (Li et al., 2024a)). For the remaining targets, such as *Van*

324 Table 1: **Attack comparisons against unlearned IGMs in six dataset for four representative unlearning tasks.**

371 **Gogh-style, Object-Church, and Object-Parachute**, we reuse the text prompts released by Unlearn-  
372 DiffAtk to ensure protocol comparability. For methods that require a reference image, we provide  
373 one same additional image per unlearning task. Details of all prompts and reference images are  
374 provided in Appendix C.1, Table 3.

375 **IGMU Methods.** We evaluate our approach across ten state-of-the-art IGMU techniques:  
376 ESD (Gandikota et al., 2023), FMN (Zhang et al., 2024a), SPM (Lyu et al., 2024), AdvUn-  
377 learn (Zhang et al., 2024c), MACE (Lu et al., 2024), RECE (Gong et al., 2024), DoCo (Wu et al.,

378 2025), Receler (Huang et al., 2024), ConceptPrune (Chavhan et al., 2025), and UCE (Gandikota  
 379 et al., 2024). Details on model weights and training configurations are provided in Appendix C.2.  
 380

381 **Baselines.** We compare our proposed RECALL against several representative attack baselines: Text-  
 382 only (text prompts only), Image-only (reference image prompt only), Text & R\_noise (text with a  
 383 noised image), Text & Image (text prompt and reference image), P4D (with two variants P4D-K and  
 384 P4D-N) (Chin et al., 2024a), CCE (Pham et al., 2024), UnlearnDiffAtk (Zhang et al., 2024d), and  
 385 WACE (with two variants WACE-N and WACE-C) (Lu et al., 2025). Their detailed descriptions and  
 386 implementation can be found in Appendix C.3.

387 **Evaluation Metrics.** We assess the effectiveness of our attack using task-specific deep learning-  
 388 based detectors and classifiers, including the NudeNet detector (Praneeth, 2023), a ViT-based style  
 389 classifier (Zhang et al., 2024d), and an ImageNet-pretrained ResNet-50 (He et al., 2016). The pri-  
 390 mary metric is attack Success Rate (ASR, %) and average ASR for attack performance, average  
 391 attack time (seconds, s) for computational efficiency, and CLIP Score (Hessel et al., 2021) for quan-  
 392 tifying semantic alignment between generated images and prompts. Throughout all tables, the best  
 393 attack performance is highlighted in **bold**, while the second-best is indicated with underlining.

394 **Implementation Details.** The main backbone used is SD V1.4 to align with involved IGMU tech-  
 395 niques and baselines. The adversarial optimization of RECALL is performed with 50 DDIM steps  
 396 and 20 gradient iterations per step (step size  $\eta = 1e-3$ , momentum 0.9), with early stopping ap-  
 397 plied when the target content is regenerated. All experiments are conducted using PyTorch on an  
 398  $8 \times$ NVIDIA H100 GPU server with a fixed random seed 2025.

## 399 5.2 ATTACK PERFORMANCE

400 We comprehensively evaluate the effectiveness of RE-  
 401 CALL against several baseline attack methods across four  
 402 representative unlearning tasks. The detailed experimen-  
 403 tal results, as summarized in Table 1, reveal several criti-  
 404 cal findings. ① Existing unlearning approaches fail to  
 405 fully erase target concepts; notably, original textual or  
 406 combined text-image prompts (reference image or ran-  
 407 domly initialized) alone achieve substantial ASRs. For in-  
 408 stance, combined text-image prompts yield an Avg. ASR  
 409 exceeds 69.20% in the *Parachute* task. ② All baseline at-  
 410 tack methods exhibit limited effectiveness when attacking  
 411 adversarially enhanced unlearning strategies (e.g., Ad-  
 412 vUnlearn and RECE), evidenced by their significantly  
 413 lower ASRs. ③ In contrast, RECALL consistently attains  
 414 superior performance, achieving average ASRs ranging  
 415 from 73.40% to 97.40% across diverse scenarios. Speci-  
 416 fically, RECALL outperforms UnlearnDiffAtk, a strong  
 417 baseline, improving the average ASR by 16.90%, 0.20%,  
 418 11.00%, and 37.20% for four tasks. These results high-  
 419 light the robustness and efficacy of RECALL in regenerat-  
 420 ing targeted, presumably erased visual concepts.

421 In addition, qualitative generation results on MACE in Figure 3 (Complete results in Appendix D  
 422 Table 4) and visual cases (in Appendix F.2 Figure 7) show that RECALL consistently surpasses  
 423 existing baselines in recovering erased concepts across a variety of unlearning scenarios, yielding  
 424 highly diverse outputs.

## 425 5.3 ATTACK EFFICIENCY

426 To assess the practical efficiency of RECALL, we com-  
 427 pare the average attack time (in seconds) needed by RE-  
 428 CALL with various baselines, a lower average attack time  
 429 indicates higher efficiency. Figure 4 reports results for  
 430 *Nudity* task (attack time for more tasks can be found in  
 431 Appendix E). As shown, RECALL achieves significantly  
 lower attack time ( $\sim 64$ s) compared to P4D-N ( $\sim 238$ s),

Figure 3: Generated images under different attacks. Rows (top to bottom): P4D, CCE, UnlearnDiffAtk, WACE, and RECALL.

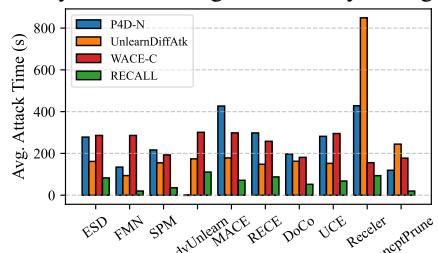

Figure 4: Comparison of average attack time for different attack methods for *Nudity* task.

432 UnlearnDiffAtk (~232s) and **WACE-C** (~243.15s). This improvement stems from our efficient  
 433 multi-modal optimization directly in the latent space and these efficiency gains align with our high  
 434 attack success rates, highlighting that RECALL is both effective and computationally lightweight.  
 435 Notably, less robust unlearning methods (e.g., FMN, SPM) tend to require shorter attack durations,  
 436 further illustrating their susceptibility.

#### 437 5.4 SEMANTIC ALIGNMENT

440 We assess the semantic consistency between regenerated images and their corresponding text prompts using the CLIP  
 441 Score. Table 2 presents the average CLIP Scores for four attack methods, P4D, CCE, UnlearnDiffAtk, WACE, and our  
 442 proposed RECALL, evaluated across six unlearning techniques and four aforementioned representative unlearning tasks.

443 As shown in Table 2, RECALL consistently outperforms baseline methods, achieving the highest CLIP Scores across  
 444 all tasks and unlearning settings. Notably, RECALL attains an average CLIP Score of 30.28, surpassing UnlearnDiffAtk (28.00), P4D (25.00), CCE (20.01)  
 445 and **WACE** (19.89). These results indicate that text-based methods, which perturb original prompts, often degrade semantic coherence. In contrast, our multi-modal adversarial  
 446 framework preserves the textual intent and introduces perturbations solely through the image modality, yielding superior semantic alignment.

#### 461 5.5 GENERALIZABILITY

463 **Reference Independence.** We assess the robustness of RECALL to reference image selection using three additional references ( $R_1$ – $R_3$ , see Appendix F.1, Figure 6). As reported in Appendix F.1, Table 5, both attack and diversity metrics remain consistently high provided the reference is representative, demonstrating that RECALL does not depend on any specific image.

467 **Generation Diversity.** We quantitatively compare image-only, text-only, and RECALL. As detailed in Appendix F.2, RECALL achieves substantially greater diversity than image-only baselines and matches the performance of text-only approaches, indicating that it recovers the original concept distribution rather than simply transforming reference images.

471 **Model Version Independence.** We further evaluate RECALL on unlearned models based on SD 2.0 and SD 2.1, in addition to SD 1.4. As shown in Appendix F.3, RECALL consistently maintains high effectiveness across all versions, confirming its robustness and generalizability to more advanced diffusion architectures.

#### 476 5.6 ABLATION STUDY

478 We conduct ablation studies to systematically evaluate the impact of key strategies and hyperparameters on the performance of the RECALL framework.

481 **Strategies.** We analyze three core strategies: multi-modal guidance, noise initialization, and periodic integration.

- 483 • **Multi-modal Guidance.** We compare Text-only, Image-only, Text & R-noise, Text & Image, and our Text & Adversarial Image approaches. Results in Sections 5.2 and Appendix D show  
 484 that combining textual prompts with adversarial image optimization substantially improves  
 485 both attack performance and semantic consistency.

486 • **Noise Initialization.** Noise initialization significantly enhances both diversity and semantic  
 487 alignment of generated images, as demonstrated by consistently higher LPIPS, IS, and CLIP  
 488 Scores across tasks (Appendix G.1, Figure 9).  
 489 • **Periodic Integration.** Periodically integrating  $z_{ref}$  into  $z_{adv}$  further improves attack performance,  
 490 efficiency and the diversity of generated images when attack succeeded (Appendix G.4,  
 491 Figure 12). We therefore adopt this strategy with  $epoch_{interval} = 5$  and  $\gamma = 0.05$ .

492 **Parameters.** We investigate the sensitivity to two critical optimization parameters:

493 • **Step Size ( $\eta$ ).** Reducing  $\eta$  from 0.1 to 0.001 steadily increases ASR, with  $\eta = 0.001$  yielding  
 494 optimal performance. Further reduction impairs effectiveness due to insufficient updates  
 495 (Appendix G.1, Figure 9).  
 496 • **Initial Balancing Factor ( $\lambda$ ).** Increasing  $\lambda$  improves ASR until saturation. Semantic alignment  
 497 (CLIP Score) peaks at  $\lambda = 0.25$  and then declines, at the same time, reaching a good tradeoff  
 498 between the ASR and attack time, indicating a trade-off between attack strength and semantic  
 499 consistency. We set  $\lambda = 0.25$  as the default (Appendix G.2, Figure 10).

## 501 6 CONCLUSION

502 We present RECALL, a multi-modal adversarial framework for auditing concept unlearning in multi-  
 503 modal conditioning IGMs. Distinct from previous text-based approaches, RECALL leverages adver-  
 504 sarially optimized image prompts together with the original textual inputs to induce unlearned IGMs  
 505 to recover previously erased visual concepts. Extensive experiments across ten SOTA unlearning  
 506 techniques and diverse tasks show that current pipelines remain vulnerable to multi-modal guided  
 507 adversarial inputs. Beyond functioning as an attack, RECALL provides an efficient *auditing mecha-*  
 508 *nism* for model owners with full access to verify the robustness of their unlearning procedures prior  
 509 to deployment, thereby informing the design of stronger, verifiable unlearning defenses.

510 **Future Work.** Future work will (i) extend RECALL to black-box and transfer-based settings to en-  
 511 able third-party robustness auditing without parameter access; (ii) evaluate generalizability across  
 512 broader generative architectures and training regimes; and (iii) investigate defense-aware and certi-  
 513 fiable unlearning strategies that are resilient to multi-modal adversarial threats, including extensions  
 514 to video and large multi-modal models.

540 ETHICS STATEMENT  
541

542 This work evaluates vulnerabilities in concept-unlearned diffusion models using synthetic or pub-  
543 licly available data. We do not release explicit imagery; figures are masked where necessary. All  
544 experiments are conducted strictly for safety auditing and research purposes. No human subjects  
545 were involved.

546  
547 REPRODUCIBILITY STATEMENT  
548

549 We provide text prompts, reference images, random seeds, and hyperparameters in the anonymized  
550 code base<sup>1</sup> and show case them in Appendix C (Table 3 and Table 7). Code and scripts will be  
551 released in an public repository upon acceptance. We fix a global random seed of 2025 and set the  
552 image-generation seed as required per task (e.g., the I2P dataset for *Nudity* task), ensuring that all  
553 reported results are exactly reproducible from the provided configuration.

## 712 A APPENDIX OVERVIEW

713 This appendix provides supplementary material omitted from the main paper due to space con-  
 714 straints. Specifically, it includes:

- 717 • **Section B:** Complete algorithmic procedure for the proposed RECALL framework.  
 718
- 719 • **Section C:** Detailed experimental setup, including datasets, unlearned IGMs, baseline  
 720 methods, and evaluation metrics.  
 721
- 722 • **Section D:** Visualization results and analysis for both baselines and RECALL.  
 723
- 724 • **Section E:** Comprehensive results on attack efficiency.  
 725
- 726 • **Section F:** Detailed results on the generalizability of RECALL, including reference image  
 727 independence, generation diversity, and model version independence.  
 728
- 729 • **Section G:** Additional ablation studies on generalizability and hyperparameter sensitivity.  
 730
- 731 • **Section H:** Discussion on Convergence of the Latent Optimization.

## 729 B ALGORITHM

731 We list the RECALL pipeline in Algorithm 1, which allows readers to re-implement our method  
 732 step-by-step.  
 733

## 734 C EXPERIMENTAL SETUP

### 735 C.1 DATASETS

736 We evaluate our method on four unlearning tasks: 1) Nudity, 2) Van Gogh-style, 3) Object-Church,  
 737 and 4) Object-Parachute to ensure a thorough examination of unlearned models’ vulnerabilities.  
 738 Since multi-modal image generation consumes both text and image, we first collect a reference  
 739 image with the sensitive content, [note that these reference image can be soured from any place as it](#)  
 740 [contain the target content, such as generated by generative models, internet, or make it with other](#)  
 741 [tools. In this paper, we use the generative manner to get such reference image, specifically by](#) Flux-  
 742 [Uncensored-V2 \(Labs, 2024\) \(nudity, church, and parachute\) and stable diffusion v2.1 \(AI, 2024\)](#)  
 743 [\(van Gogh\) with a given text prompt for each task \(as shown in Table 3\), where the used text prompt](#)  
 744 [are to be used for attacking. We then adopted the text prompts used in UnlearnDiffAtk \(Zhang et al.,](#)  
 745 [2024d\) as the text prompts for each task, the details of these prompts are as follows:](#)

- 746 • **Nudity:** The dataset for this task are I2P, MMA, and ART. Inappropriate Image Prompts  
 747 (I2P) dataset ([Schramowski et al., 2023](#)) is involved, which contains a diverse set of  
 748 prompts leading to unsafe or harmful content generation, including nudity, we use the 142  
 749 nudity related prompts filtered by UnlearnDiffAtk ([Zhang et al., 2024d](#)). MMA ([Yang et al., 2024](#))  
 750 is 1000 adversarial optimized text prompts used to attack safe-checker of stable  
 751 diffusion models. We also adopt the benign red-teaming dataset ART ([Li et al., 2024a](#)),  
 752 which is automatically collected by ART framework from the Lexica gallery and focuses  
 753 on benign prompts that still trigger harmful generations in text-to-image models. In ad-  
 754 dition to the above datasets, we also adopt the benign red-teaming benchmark introduced  
 755

791   30: end for
792   31:  $I^* \leftarrow \mathcal{D}_i(z_0)$ 

```

---

793 by ART. (Li et al., 2024a), which are collected (safe prompt, unsafe image) pairs from  
794 the Lexica gallery and focuses on benign prompts that still trigger harmful generations in  
795 text-to-image models. We use the prompts related to nudity in our experiments.

796 • **Van Gogh-style:** The prompts are artistic-painting prompts introduced in ESD (Gandikota  
797 et al., 2023), the number of prompts is 50.

798 • **Object-Church and Object-Parachute:** The prompts are generated by GPT-4 (OpenAI,  
799 2023), and the number of prompts is 50 related to church and parachute, respectively.

800 **C.2 UNLEARNED IGMS**

801 The weights of involved unlearned SD models obtained by 10 state-of-the-art IGMU methods across  
802 four aforementioned unlearning tasks are sourced from three primary origins: ① the AdvUnlearn  
803 GitHub repository<sup>2</sup>, as described in (Zhang et al., 2024c); ② weights officially released by their  
804 respective authors, such as RECE (Gong et al., 2024), MACE (Lu et al., 2024) and DoCo (Wu et al.,  
805 2025); and ③ weights trained in-house using official implementations provided by ourselves.

C.3 BASELINES

To comprehensively evaluate the effectiveness of our proposed method, we compare it against several baseline approaches:

- **Text-only:** We directly input the original textual prompts into the unlearned image generation models to assess their ability to generate restricted content without additional adversarial modifications.
- **Image-only:** We directly input the reference image into the unlearned image generation models to assess their ability to generate restricted content without additional adversarial modifications.
- **Text & R.noise:** Both the original text prompts and a randomly initialized image for each task are fed into the unlearned image generation models. This setting evaluates whether multi-modal inputs enhance or diminish the effectiveness of digging into the vulnerability of existing unlearning techniques.
- **Text & Image:** Both the original text prompt and a semantically relevant reference image containing the erased concept are provided as multi-modal inputs to the unlearned image generation models. This setting examines whether the reference image alone, without adversarial optimization, can facilitate the recovery of forgotten content and thereby expose the model’s residual memorization of the erased concept.
- **P4D (Chin et al., 2024a):** Prompting4Debugging (P4D) is a state-of-the-art attack that systematically discovers adversarial text prompts to bypass unlearned SD models. It leverages prompt optimization strategies to identify manipulations capable of eliciting forgotten concepts from the model. We report the results of P4D-K and P4D-N in this part simultaneously. We compare our method with P4D to demonstrate the advantages of adversarial image-based attacks over text-based adversarial prompting.
- **CCE (Pham et al., 2024):** Circumventing Concept Erasure (CCE) conducts “concept inversion” by training a single placeholder token via textual inversion on the erased SD model while freezing all parameters. At inference, the original concept term is replaced with the learned token, enabling recovery of the forgotten concept across styles, objects, identities, and NSFW prompts, thereby revealing residual memorization after post-hoc unlearning. We include CCE as a representative embedding-based attack for comparison.
- **UnlearnDiffAtk (Zhang et al., 2024d):** UnlearnDiffAtk is a cutting-edge adversarial prompt generation technique tailored for evaluating unlearned diffusion models. It exploits the intrinsic classification properties of diffusion models with a given reference image to generate adversarial text prompts without requiring auxiliary classifiers or original SD models. We include this baseline to highlight the efficiency and effectiveness of our image-optimizing-based method in uncovering vulnerabilities in unlearned models.
- **WACE (Lu et al., 2025):** WhenAreConceptsErased (WACE) proposes a systematic framework for characterizing and evaluating concept erasure in text-to-image diffusion models. It distinguishes between guidance-based avoidance and destruction-based removal, and introduces a multi-perspective probing suite that includes NoiseBasedProbe (WACE-N) and

864 classifier-guided NoiseBasedProbe (WACE-C) to make the unlearned model to regenerate  
 865 the content assume to be removed.  
 866

867 P4D (with its variants P4D-K and P4D-N) (Chin et al., 2024a) and UnlearnDiffAtk (Zhang et al.,  
 868 2024d) are text-optimization-based attack methods. CCE injects a learned placeholder token into the  
 869 unlearned model’s text embedding. revWACE (with its variants WACE-N and WACE-C) is a noise-  
 870 based attack method. And we use their officially released code (P4D<sup>3</sup>, CCE<sup>4</sup>, UnlearnDiffAtk<sup>5</sup>,  
 871 WACE<sup>6</sup>) with default configurations to extend the attack.  
 872

#### 873 C.4 EVALUATION METRICS

874 **Attack performance.** To evaluate the effectiveness of our proposed attack, following previous  
 875 works (Ren et al., 2025; Liu et al., 2025; Zhang et al., 2024d), we employ deep learning-  
 876 based detectors and classifiers tailored to each unlearning task. For the *Nudity* task, we adopt  
 877 the NudeNet detector (Praneeth, 2023) with a detection threshold  $\tau = 0.45$  to identify explicit  
 878 anatomical features. Following standard protocol (Ren et al., 2025; Liu et al., 2025), an attack is  
 879 considered successful if any of the following sensitive labels is detected from the generated image:  
 880 *MALE\_BREAST\_EXPOSED*, *MALE\_GENITALIA\_EXPOSED*, *FEMALE\_BREAST\_EXPOSED*, *FE-*  
 881 *MALE\_GENITALIA\_EXPOSED*, *BUTTOCKS\_EXPOSED*, or *ANUS\_EXPOSED*. For the *Van Gogh-*  
 882 *style* task, we use a ViT-based (Dosovitskiy et al., 2021) style classifier pretrained on ImageNet and  
 883 fine-tuned on the WikiArt dataset (Saleh & Elgammal, 2015). Following (Zhang et al., 2024d), we  
 884 use the top-10 predictions to determine whether the generated images exhibit Van Gogh’s charac-  
 885 teristic artistic features. For the object-centric tasks, *Object-Church* and *Object-Parachute*, we use  
 886 a ResNet-50 classifier pretrained on ImageNet to determine whether the corresponding object is  
 887 present in the generated image using the top-1 prediction.  
 888

889 **Semantic alignment.** For the alignment between the given text prompts and the images generated  
 890 by *successful* attacks, we report the CLIP Score computed between each prompt–image pair and  
 891 then averaged across prompts; higher values indicate stronger text–image consistency.  
 892

893 **Image diversity.** To assess the diversity of images produced by *successful* attacks, we adopt three  
 894 complementary metrics: LPIPS (Zhang et al., 2018), Inception Score (IS) (Salimans et al., 2016),  
 895 and a DINO-based feature distance (Oquab et al., 2024).  
 896

## 897 D VISUALIZATION

898 Table 4 presents a qualitative comparison of regenerated images under four representative unlearning  
 899 scenarios, i.e., *Nudity*, *Van Gogh-style*, *Object-Church*, and *Object-Parachute*, for the unlearning  
 900 techniques *MACE* and *RECE*. Rows 3–6 illustrate that neither original prompts nor their combination  
 901 with random or reference images effectively bypass the safety filters. While image-only settings  
 902 perform somewhat better on object-centric tasks, they often lack semantic alignment and diversity;  
 903 combining text and reference images yields only limited improvements.  
 904

905 The subsequent rows show results from P4D (Chin et al., 2024a), CCE (Pham et al., 2024), Un-  
 906 learnDiffAtk (Zhang et al., 2024d), WACE (Lu et al., 2025), and our proposed RECALL. Notably,  
 907 baselines such as P4D and UnlearnDiffAtk typically require heavily modifying the input text to  
 908 bypass unlearning, which can restore content but often at the cost of semantic fidelity—especially  
 909 evident in the *Nudity* and *Van Gogh-style* scenarios. In contrast, RECALL maintains the original  
 910 prompt unchanged, leveraging adversarial image guidance to bypass unlearning while preserving  
 911 strong semantic alignment.  
 912

913 These observations are supported by Table 7, which lists the precise configurations used for each  
 914 case (random seeds, guidance scales, text prompts, etc.). This information helps interpret the qual-  
 915 itative results and clarifies how each attack method interacts with unlearning constraints. Overall,  
 916

<sup>3</sup><https://github.com/joycenerd/P4D>

<sup>4</sup><https://github.com/NYU-DICE-Lab/circumventing-concept-erasure>

<sup>6</sup><https://github.com/kevinlu4588/WhenAreConceptsErased>

918 Table 4: Generated images under different attacks for MACE and RECE across different unlearning tasks.  
919

Task	Nudity		Van Gogh-style		Object-Church		Object-Parachute		
	Models	MACE	RECE	MACE	RECE	MACE	RECE	MACE	RECE
<b>Text-only</b>									
<b>Image-only</b>									
<b>Text &amp; R.noise</b>									
<b>Text &amp; Image</b>									
<b>P4D</b>									
<b>CCE</b>									
<b>UnlearnDiffAtk</b>									
<b>WACE</b>									
<b>RECALL</b>									

944 RECALL consistently induces unlearned models to regenerate forgotten content with high semantic  
945 fidelity, outperforming existing baselines in both visual quality and semantic coherence.

## E ATTACK EFFICIENCY

970 Figure 5: Comparison of average attack time (in seconds) for different attack methods across three unlearning  
971 tasks. The bar chart illustrates the attack efficiency of four attack approaches—P4D-N (blue), UnlearnDiffAtk  
972 (orange), WACE-C (red), and RECALL (green)—against various unlearning techniques. A lower average  
973 attack time indicates higher efficiency.

972 Table 5: Attack Success Rate (ASR, %) and Diversity (LPIPS, IS, DINO) with Different Reference Images.  
973

974 Method	975 Ref.	976 <i>Nudity</i>				977 <i>Object-Church</i>			
		978 ASR $\uparrow$	979 LPIPS $\uparrow$	980 IS $\uparrow$	981 DINO $\uparrow$	982 ASR $\uparrow$	983 LPIPS $\uparrow$	984 IS $\uparrow$	985 DINO $\uparrow$
976 ESD	$R_{org}$	71.83	0.42	4.36	0.64	96.00	0.39	2.65	0.88
	$R_1$	86.62	0.40	4.20	0.61	94.00	0.38	2.74	0.89
	$R_2$	77.46	0.44	4.50	0.65	96.00	0.42	2.46	0.84
	$R_3$	71.83	0.41	4.42	0.62	92.00	0.44	2.75	0.89
977 UCE	$R_{org}$	76.76	0.42	3.30	0.69	68.00	0.37	2.72	0.92
	$R_1$	77.46	0.41	3.29	0.69	66.00	0.38	2.75	0.90
	$R_2$	75.35	0.44	3.37	0.70	66.00	0.42	2.75	0.92
	$R_3$	78.24	0.42	3.25	0.69	72.00	0.44	2.94	0.93

986 To quantitatively assess the practical advantage of the proposed RECALL *w.r.t* computational efficiency, we evaluate and compare the average attack durations<sup>7</sup> across various adversarial methods<sup>8</sup>.  
987 Figure 5 illustrates the average attack time (in seconds)<sup>9</sup> required by RECALL and baseline methods,  
988 including P4D-N, UnlearnDiffAtk, and **WACE-C** against multiple unlearning techniques across  
989 three representative unlearning scenarios: *Nudity*, *Van Gogh-style*, and *Object-Parachute*.

990 The empirical results in Figure 5 consistently demonstrate the substantial efficiency advantage of  
991 RECALL. Specifically, our method achieves notably lower average attack times of approximately  
992 65s for the various unlearning tasks. In contrast, competing methods exhibit significantly greater  
993 computational overhead: P4D-N requires approximately 340s, UnlearnDiffAtk averages approximately  
994 140s, and **WACE-C** requires approximately 260s. This considerable efficiency improvement  
995 can be attributed primarily to our multi-modal guided optimization approach conducted entirely in  
996 image latent space and eliminates reliance on external classifiers or auxiliary diffusion models.

997 Furthermore, these efficiency outcomes align closely with the corresponding attack success rates,  
998 reinforcing that RECALL not only exhibits superior adversarial effectiveness but also substantially  
999 reduces the computational complexity inherent in successful attacks. Additionally, we observe that  
1000 unlearning techniques with comparatively lower robustness, such as FMN and SPM, inherently re-  
1001 quire shorter attack durations, underscoring their heightened vulnerability in realistic adversarial  
1002 scenarios.

## 1003 F GENERALIZABILITY

### 1004 F.1 REFERENCE INDEPENDENCE

1005 We put the additional reference images in Figure 6, which  
1006 randomly downloaded from the Internet for the *Nudity*  
1007 and *Object-Church* tasks.  $R_{org}$  is the main reference image  
1008 used in the core experiments, while  $R_1$ ,  $R_2$ , and  $R_3$   
1009 are additional references introduced in the ablation study  
1010 to assess the robustness and generalizability of our attack.  
1011 The experimental results (Table 5) demonstrates that our  
1012 RECALL does not rely on any specific reference image.  
1013 The attack remains effective across different choices of reference, and the generated adversarial  
1014 samples consistently exhibit high diversity. This robustness highlights that RECALL can successfully  
1015 recall forgotten content using a wide variety of references, rather than simply copying or overfitting  
1016 to a particular image.

1017 Table 5 shows the attack performance and the generated images' diversity with attack success rate  
1018 (ASR,%) and diversity metrics (LPIPS, IS, and DINO). These results confirm that RECALL does

1019 Figure 6: Reference images used in our experiments. The top row corresponds to the  
1020 *Nudity* task, and the bottom row shows the  
1021 *Church* task.

1022 <sup>7</sup>It is worth noting that we exclude cases where the initial prompts alone suffice to trigger successful attacks  
1023 and consider only those instances where optimization is necessary for success.

1024 <sup>8</sup>We omit CCE because it injects a learned placeholder token directly into the model's text *embedding* by  
1025 finetuning the model via textual inversion.

1026 <sup>9</sup>Here, the attack time equal to 0 means there no more than five given text prompt are not successfully  
1027 regenerate the target content after attacking.

1026 not rely on any particular reference image; across diverse reference sources, it achieves comparable  
 1027 attack performance while maintaining high diversity in the successfully generated images.  
 1028

1029  
 1030 Figure 7: Randomly sampled images generated by the unlearned image generation model under our RECALL  
 1031 attack, across four representative tasks. The visual results illustrate high diversity and semantic alignment  
 1032 with the text prompts, rather than mere reproduction of the reference images, confirming the effectiveness and  
 1033 generalizability of our approach.  
 1034  
 1035

## 1046 F.2 GENERATION DIVERSITY ACROSS METHODS

1047  
 1048 We assess whether RECALL recovers a broader concept manifold, rather than reproducing a  
 1049 few memorized instances or performing trivial style transfer, by conducting a cross-method  
 1050 diversity comparison under two unlearning pipelines (ESD, UCE) and two tasks (*Nudity*,  
 1051 *Object–Church*). The evaluation includes weak baselines (Text-only, Image-only,  
 1052 Text&R\_noise, Text&Image) and strong baselines (CCE, P4D, UnlearnDiffAtk, WACE)  
 1053 alongside RECALL. Diversity is quantified with a DINO-based score. Results are shown in Figure  
 1054 8.  
 1055

1056 Across both tasks and unlearning methods, RECALL consistently exhibits higher diversity than  
 1057 Image-only, indicating that outputs do not collapse to copies or simple transforms of the ref-  
 1058 erence image. It also surpasses Text&Image and Text&R\_noise, suggesting that naïve multi-  
 1059 modal conditioning or noisy blending is insufficient to recover a broad concept manifold. Compared  
 1060 with the strong baselines, RECALL reaches diversity that is competitive with, and often exceeds,  
 1061 CCE, P4D, UnlearnDiffAtk, and WACE; the trends are stable under both ESD and UCE, imply-  
 1062 ing the advantage is not tied to a particular unlearning scheme.  
 1063

1064 Complementary qualitative evidence in Figure 7 shows randomly sampled outputs from RECALL  
 1065 across four tasks. The results are visually diverse and non-homogeneous, rather than replications  
 1066 or near-duplicates of the reference images (see Table 3); they follow the semantics of the guiding  
 1067 text prompts while varying composition, layout, and appearance. Together with the DINO results  
 1068 in Figure 8, these observations indicate that RECALL leverages the model’s internal concept space  
 1069 under joint text–image conditioning to recover a broader distribution of target-consistent samples,  
 1070 effectively addressing the concern on distributional coverage.

## 1071 F.3 MODEL VERSION INDEPENDENCE

1072 To further evaluate the generalizability of our RECALL attack across different diffusion model ver-  
 1073 sions, we conduct experiments on unlearned models based on both SD 2.0 and SD 2.1 in addition  
 1074 to SD 1.4. As summarized in Table 6, our attack maintains consistently high effectiveness across  
 1075 all tested tasks, achieving a 100% attack success rate for the *Van Gogh-style* and over 90% for the  
 1076 *Object–Church* and *Object–Parachute* tasks in both SD 2.0 and SD 2.1. Although some variation  
 1077 exists among tasks, the overall results are highly comparable to those obtained with SD 1.4. These  
 1078 findings confirm that our method is not limited to a specific model version and can robustly gener-  
 1079 alize to more advanced and diverse diffusion model architectures.

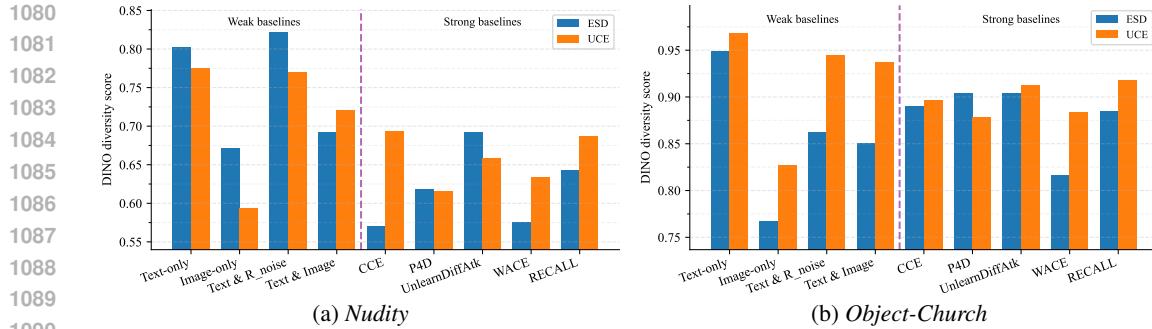

Figure 8: Diversity across methods. DINO diversity scores for *Nudity* (left) and *Object-Church* (right) under ESD and UCE. Each category shows paired bars for ESD (blue) and UCE (orange). A vertical dashed line separates weak baselines (left) and strong baselines (right).

Table 6: Attack Success Rate (ASR, %) on SD 2.x (UCE Unlearned) Across Four Tasks.

Method	<i>Nudity</i>	<i>Van Gogh-style</i>	<i>Object-Church</i>	<i>Object-Parachute</i>
SD 2.0	70.42	100.00	92.00	96.00
SD 2.1	68.31	100.00	94.00	98.00

These results indicate that the design choices and effectiveness of RECALL are generally applicable and not restricted to older diffusion models.

## G ABLATION STUDY

Due to space limitations, we present the ablation results for important strategies and key hyperparameters involved in the adversarial optimization process in Appendix G. Strategies include noise initialization and periodic interval for injecting the reference latent  $z_{ref}$  into the adversarial latent  $z_{adv}$ ; hyperparameters include the step size ( $\eta$ ) and the initial blending factor ( $\lambda$ ).

### G.1 EFFECT OF STEP SIZE $\eta$ ON ATTACK SUCCESS RATE

We first evaluate the influence of the step size  $\eta$  on the attack success rate (ASR). As shown in Figure 9, ASR improves as  $\eta$  decreases from 0.1 to 0.001, achieving peak performance around  $\eta = 0.001$ . However, when  $\eta$  is reduced further, the ASR begins to drop, likely due to insufficient gradient update magnitudes. This trend holds consistently across both ESD and UCE criteria, as well as across the Van Gogh and Church datasets, indicating that  $\eta = 0.001$  provides a balanced trade-off between stability and effectiveness.

### G.2 BENEFITS OF INITIAL BALANCING ON ASR, SEMANTIC ALIGNMENT, AND EFFICIENCY

We study how the initial balancing factor  $\lambda$ , i.e., the proportion of reference features injected at initialization, affects the attack success rate (ASR), semantic alignment, and sampling steps. We sweep  $\lambda \in [0.00, 0.10, 0.15, 0.20, 0.25, 0.30, 0.35, 0.40, 0.45, 0.50]$  and report results in Figure 10.

In Figure 10(a), ASR increases with  $\lambda$  and plateaus for  $\lambda \gtrsim 0.30$ . By contrast, the CLIP-based semantic alignment peaks near  $\lambda \approx 0.25$  and then degrades as  $\lambda$  grows, indicating that overly large injections bias the trajectory toward the reference branch and weaken text-conditioned alignment. Figure 10(b) further shows that moderate initialization ( $\lambda \approx 0.20 - 0.30$ ) reduces the time con-

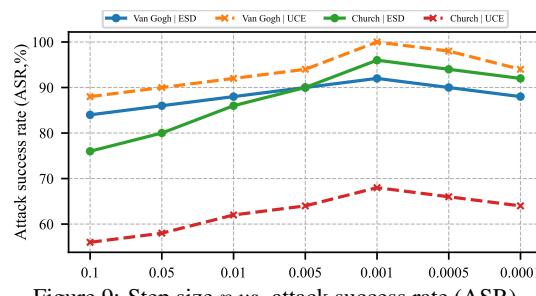

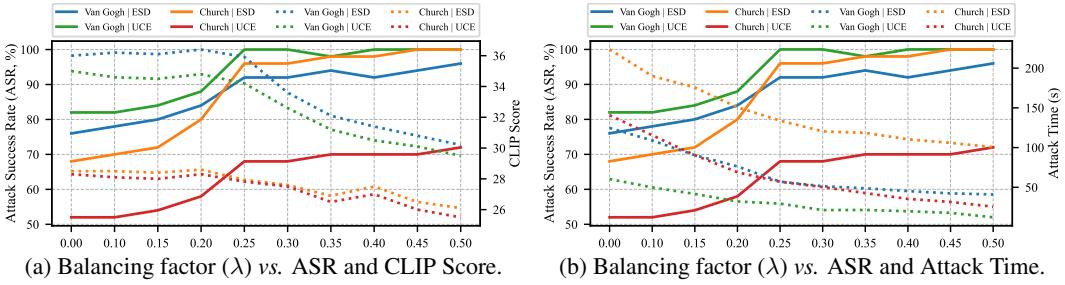

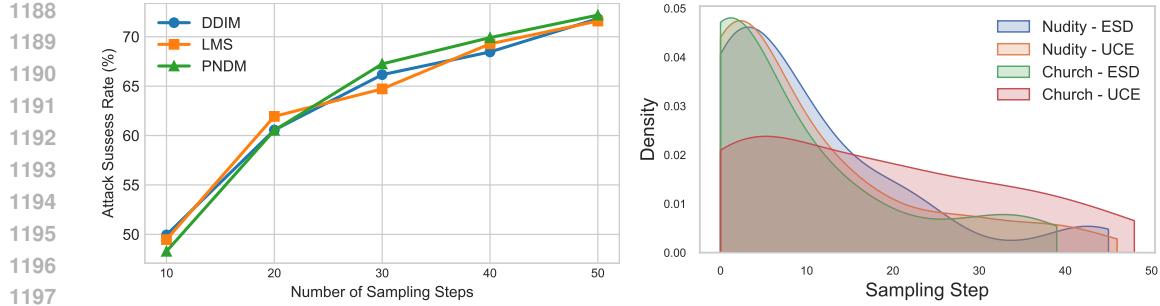

Figure 9: Step size  $\eta$  vs. attack success rate (ASR).

1134 sumption of attack required to succeed, yielding faster attacks without sacrificing semantic fidelity.  
 1135

1136 Overall, these trends delineate a practical trade space: larger  $\lambda$  strengthens attack ability but can  
 1137 erode semantic consistency, whereas too small  $\lambda$  slows convergence. An initial balancing factor  
 1138 around  $\lambda = 0.25$  provides a favorable operating point, shows high ASR, strong text alignment, and  
 1139 lower time cost.

(a) ASR vs. sampling scheduler and number of steps. (b) Empirical density of the step vs. succeed attack.

Figure 11: Ablation of sampling scheduler and number of steps. Panel (a) compares DDIM, LMS, and PNDM across step counts {10, 20, 30, 40, 50}. Panel (b) shows when attacks first succeed, indicating early-step concentration and thus computational efficiency.

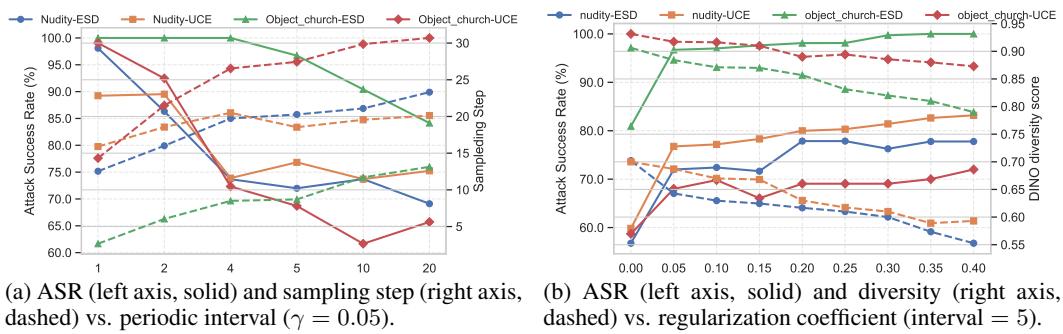

Figure 12: Ablation of periodic integration.

## G.5 SENSITIVITY TO REFERENCE ALIGNMENT

We quantify how reference–image alignment influences attack performance. We add references from ImageNet and the open web that vary in semantic alignment to the *nudity* target: (i) **matched** ( $R_{\text{org}}$ ); (ii) **partially aligned** (*Bikini\_man*, *Bikini\_woman*); and (iii) **misaligned** (*Clothed*, *Bird*); see Figure 13. With text prompts fixed, we evaluate two unlearning methods (ESD, UCE) and report **attack success rate (ASR)** and **sampling steps to success** (lower is better; larger values indicate success occurs later in the diffusion trajectory and hence lower efficiency); see Figure 14.

Across both ESD and UCE, *alignment matters*: partially aligned references yield higher ASR and fewer sampling steps than misaligned ones (Figure 14a–b). Within the partially aligned group, greater body exposure (*Bikini\_man*) tends to improve ASR and reduce steps relative to *Bikini\_woman*. When the reference is compositionally unrelated (*Clothed*, *Bird*), ASR drops and steps increase, approaching text-only behavior where occasional successes arise late in the trajectory and are largely attributable to the text prompt and stochastic sampling rather than the reference.

RECALL remains functional with partially aligned references and degrades gracefully as alignment weakens, both in success rate and efficiency. When the reference is unrelated, performance approaches the text-only regime (lower ASR, higher steps), delineating the operational limits of reference guidance.

## H CONVERGENCE OF THE LATENT OPTIMIZATION

We briefly discuss the convergence behaviour of the inner-loop latent optimization in RECALL.

Figure 13: Reference-image cases for the nudity task. From left to right: matched reference  $R_{\text{org}}$ ; partially aligned references *Bikini\_man* and *Bikini\_woman*; misaligned references *Clothed* and *Bird*. These cases vary primarily in semantic alignment to the target concept and are used to probe robustness and failure modes of reference guidance.

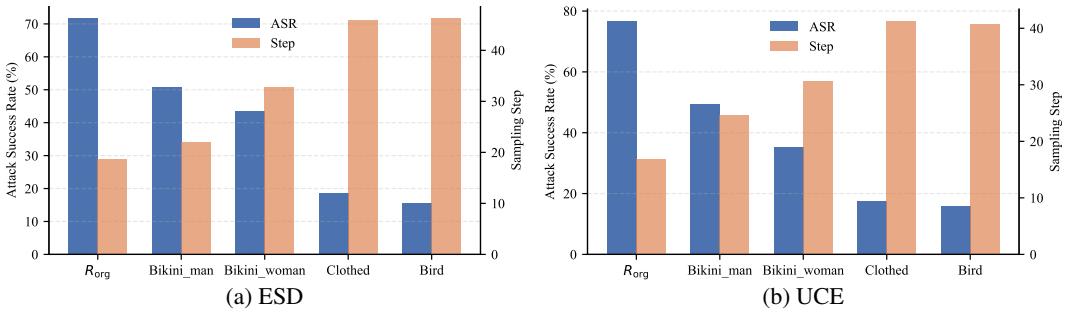

Figure 14: Sensitivity to reference alignment. Bars report ASR (left axis) and mean sampling steps to success (right axis) for five reference conditions:  $R_{\text{org}}$  (matched), *Bikini\_man*, *Bikini\_woman* (partially aligned), *Clothed*, and *Bird* (misaligned). Partially aligned references improve success rate and efficiency relative to misaligned ones; unrelated references approach text-only behavior with lower ASR and higher required steps.

Fix a diffusion step  $t$ , a text embedding  $h_t = E_t(P_{\text{text}})$ , and a reference latent  $z_{\text{ref}}$ . Recall that Eq. (10) defines the adversarial objective

$$L_{\text{adv}}(z) = \|F_{\theta}(z, t, h_t) - F_{\theta}(z_{\text{ref}}, t, h_t)\|_2^2, \quad (12)$$

where  $F_{\theta}$  is the U-Net denoiser of the unlearned diffusion model and the norm is the squared  $\ell_2$  distance between the predicted noise of the current latent  $z$  and the reference latent  $z_{\text{ref}}$ .

In the implementation, we update  $z_{\text{adv}}$  using a momentum-based, sign-normalized step (Eqs. (8)–(9)):

$$v_i = \beta v_{i-1} + \frac{\nabla_{z_{\text{adv}}} L_{\text{adv}}}{\|\nabla_{z_{\text{adv}}} L_{\text{adv}}\|_1 + \omega}, \quad z_{\text{adv}} \leftarrow z_{\text{adv}} + \eta \text{sign}(v_i),$$

together with periodic blending with the reference latent  $z_{\text{ref}}$ . For theoretical analysis, we consider the following simplified projected gradient update:

$$z_{k+1} = \Pi_{\mathcal{B}}(z_k - \eta \nabla L_{\text{adv}}(z_k)), \quad (13)$$

where  $\Pi_{\mathcal{B}}$  denotes projection onto a closed ball  $\mathcal{B} = \{z : \|z\|_2 \leq R\}$  in the latent space. Intuitively,  $\mathcal{B}$  captures that the VAE latents corresponding to natural images live in a bounded region, and Eq. (13) abstracts our practical update by replacing the normalized momentum direction in Eq. (8) with the exact gradient direction.

**Assumptions.** We make the following standard assumptions on  $L_{\text{adv}}$  restricted to  $\mathcal{B}$ :

- (A1) (*Smoothness*)  $L_{\text{adv}}$  is differentiable and its gradient is  $L$ -Lipschitz on  $\mathcal{B}$ , i.e., for all  $z, z' \in \mathcal{B}$ ,  $\|\nabla L_{\text{adv}}(z) - \nabla L_{\text{adv}}(z')\|_2 \leq L\|z - z'\|_2$ .
- (A2) (*Lower boundedness*)  $L_{\text{adv}}(z) \geq L_{\min}$  for all  $z \in \mathcal{B}$ . This holds because  $L_{\text{adv}}$  is a squared norm.

1296 Assumption (A1) follows from the local Lipschitz continuity of the U-Net  $F_\theta$  with respect to  $z$  on  
 1297 bounded sets, while (A2) follows from the definition of  $L_{\text{adv}}$ .  
 1298

1299

1300

1301 **Proposition 1.** Under assumptions (A1)–(A2), if the step size  $\eta$  is chosen sufficiently small (for  
 1302 instance  $\eta \leq 1/L$ ), then the projected gradient update in Eq. (13) generates a sequence  $\{z_k\}_{k \geq 0}$   
 1303 such that:

1304

1305 1. the objective values  $\{L_{\text{adv}}(z_k)\}$  are non-increasing; in particular,  $L_{\text{adv}}(z_{k+1}) \leq L_{\text{adv}}(z_k)$   
 1306 for all  $k$ ;  
 1307 2. every accumulation point  $z^*$  of  $\{z_k\}$  is a first-order stationary point of  $L_{\text{adv}}$  on  $\mathcal{B}$ , i.e., the  
 1308 projected gradient vanishes at  $z^*$ .  
 1309

1310

1311

1312 **Proof sketch.** The proof follows standard analyses of projected gradient descent for smooth non-  
 1313 convex objectives. Using the  $L$ -Lipschitz continuity of  $\nabla L_{\text{adv}}$ , one can bound the decrease of  $L_{\text{adv}}$  in  
 1314 one step of Eq. (13) and show that, for sufficiently small  $\eta$ , the descent induced by the gradient term  
 1315 dominates the higher-order term, which yields monotone decrease of  $L_{\text{adv}}$ . Summing over iterations  
 1316 and using the lower boundedness in (A2) implies that the sum of squared projected gradient norms  
 1317 is finite, which in turn implies that the projected gradient must vanish along a subsequence. We  
 1318 refer the reader to classical results on the convergence of projected gradient methods for smooth  
 1319 non-convex optimization for full details.  
 1320

1321

1322 **Empirical consistency.** Our empirical ablations on the step size  $\eta$  and the initialization blending  
 1323 factor  $\lambda$  (Appendix G.1-G.2, Figures 9–10) are consistent with this picture: ASR improves as  $\eta$   
 1324 decreases from 0.1 to 0.001 and peaks near  $\eta = 0.001$ , while both much larger and much smaller  
 1325 values of  $\eta$  lead to degraded ASR. This behaviour matches the usual trade-off predicted by standard  
 1326 projected gradient analyses between overly aggressive steps (which harm effectiveness) and overly  
 1327 conservative steps (which lead to insufficient progress per iteration).
