ENHANCE REASONING FOR LARGE LANGUAGE MOD ELS WITH REINFORCEMENT LEARNING IN THE GAME WEREWOLF

Anonymous authors

Paper under double-blind review

Abstract

Despite their success across a broad spectrum of general tasks, Large Language Models (LLMs) often underperform in domain-specific tasks not well-represented in their pre-training corpora. We introduce an innovative framework integrating general-purpose LLMs with an external *Thinker* module to enhance the reasoning capabilities of LLM-based agents. Unlike augmenting LLMs with prompt engineering, our Thinker module directly accesses knowledge from domain databases and employs supervised or reinforcement learning (RL). We establish a reasoning hierarchy where LLMs handle intuitive *System-1* tasks that are domain-agnostic, while the Thinker focuses on *System-2* tasks that require complex logical analysis and domain-specific knowledge. Our framework is demonstrated through a 9-player Werewolf game that necessitates dual-system reasoning. We design a communication protocol between LLMs and the Thinker, then optimize the Thinker through online RL and refine it by imitation learning. Drawing from 18800 human games, this work also contributes to the largest dataset for social deduction games to date. Experiments show that GPT-3.5 and GPT-4, augmented with the Thinker, significantly improve in deductive reasoning, textual speech generation, and online gameplay evaluated by human players. Further, integrating a fine-tuned 6B Werewolf-specific LLM with the Thinker achieves performance on par with GPT-4.

1 INTRODUCTION

The field of artificial intelligence has witnessed groundbreaking advancements in recent years, 035 with the development of Large Language Models (LLMs) (Ouyang et al., 2022; OpenAI, 2023; Anil et al., 2023). Apart from their impressive proficiency in natural language processing (NLP) 037 tasks (Thoppilan et al., 2022; Zhang et al., 2023b), LLMs also exhibit vast potential as general 038 problem solvers in areas such as planning and decision-making (Huang et al., 2022), knowledge transfer and generalization (Anil et al., 2022) and multi-modal perception (Yin et al., 2023) due to the rich world knowledge embedded in their training corpora. Consequently, the integration of LLMs 040 as central controllers with task agents for end-to-end solutions has emerged as a promising research 041 direction, yielding breakthroughs in domains including tools and assistants (Schick et al., 2023; Ge 042 et al., 2023), engineering (Ahn et al., 2022), and gaming (Wang et al., 2023). 043

LLM-based agents utilize LLMs for their general-purpose reasoning abilities (Huang & Chang, 2022),
which are primarily enabled by prompt engineering methods such as information profiling (Zhang et al., 2023a; Qian et al., 2023), step-by-step task decomposition (Wei et al., 2022b; Zhou et al., 2022),
recursive prompting by feedback from the environment (Yao et al., 2022), human interaction (Wu et al., 2022) and self-refinement (Madaan et al., 2023; Shinn et al., 2023). These methods obviate the need for domain-specific fine-tuning of LLMs. To augment their task-specific competencies, researchers adopt external modules like memory systems for storing and retrieving historical information (Lin et al., 2023; Zhong et al., 2023; Hu et al., 2023), external tools (Schick et al., 2023), APIs (Qin et al., 2023), knowledge bases (Lewis et al., 2020) and expert models (Yang et al., 2023); Ge et al., 2023).

Despite these advancements, challenges persist in domain-specific applications, where LLM-based agents often serve primarily as demonstrations rather than as practical solutions (Yang et al., 2023a;

Figure 1: Comparing related approaches. (a) Alignment by fine-tuning of LLMs (Bakhtin et al., 2022); (b) Reasoning mainly by LLMs (Xu et al., 2023b); (c) A dual-system reasoning hierarchy of LLMs and the Thinker. Snow and fire represent without/with finetuning of the model.

071

Tan et al., 2024). First, while general-purpose LLMs have emerged some reasoning capabilities, they require sufficient model scales and computational overheads (Kaplan et al., 2020), along with various aforementioned techniques (Wei et al., 2022a). However, LLMs struggle to achieve satisfactory performance in higher-level reasoning (Stechly et al., 2023; Dziri et al., 2023) and planning (Valmeekam et al., 2023; Bubeck et al., 2023) tasks. Second, most LLM-based agents avoid fine-tuning LLMs on task-specific data to preserve the model's generality and prevent over-fitting. This strategy complicates the utilization of existing domain datasets and expertise, as well as the alignment of task scenarios with input-output formats, data distributions, and human preferences.

083 Addressing the limitations of LLMs in high-level and domain-specific reasoning, we draw inspiration from the dual-process theory (Wason & Evans, 1974; Daniel, 2017; Hagendorff et al., 2022; Weston 084 & Sukhbaatar, 2023; Lin et al., 2024) and distinctly separate reasoning into two systems. We propose 085 an external *Thinker* module to enhance the reasoning capabilities of LLMs, as shown in Figure 1(c). In our framework, LLMs are responsible for System-1 reasoning related to intuitive thinking, such as 087 domain-agnostic NLP interactions, common-sense and symbolic reasoning, while the Thinker handles 088 System-2 reasoning that is deliberate, analytical, and requires deep understanding of domain-specific knowledge. We design a communication protocol between LLMs and the Thinker through explicit 090 information. Unlike augmenting LLMs with prompt engineering, the Thinker directly accesses 091 knowledge from extensive databases and applies various optimization techniques, thus enhancing the 092 performance and human alignment without compromising LLM's generality.

The 9-player Werewolf game serves as the proving ground for our framework, given that current AI systems lag significantly behind even moderately skilled human players in this popular social deduction game. We heuristically dissect the reasoning process into four stages, as illustrated in Figure 1(b). *System-1* reasoning includes natural language understanding (NLU) and generation (NLG) of players' speech. Meanwhile, the hidden identities require complex **deductive reasoning** and **strategic planning** such as deception and disguise, which fall under *System-2* reasoning. This duality creates a significant gap between the players' actual speeches and their true intentions, making Werewolf an ideal testbed for assessing advanced reasoning capabilities of LLM-based agents.

We identify primary patterns from real human speeches and design language-based features (from LLMs to Thinker) and speech instructions (from Thinker to LLMs) accordingly. The Thinker is optimized by imitation learning, reinforcement learning (RL) from fictitious self-play (Heinrich et al., 2015), and population-based training (Jaderberg et al., 2017), to produce reasonable and human-aligned game actions and instructions. We compare our approach to the Least-to-Most (LtM) prompting (Zhou et al., 2022) and 11-shot in-context learning from three dimensions: accuracy of deductive reasoning, human preference of generated speeches, and online evaluation of a complete game. Experiments show that the integration of the Thinker module substantially enhances the

reasoning and generation capability of GPT-3.5 and GPT-4. Further, we fine-tune a 6B (Du et al., 2021) werewolf-specific LLM to better align human speech styles. When augmented with the Thinker, it achieves performance comparable to that of GPT-4. Our primary contributions include:

- We propose an innovative Thinker module designed to enhance the reasoning capabilities of LLMs, demonstrated through a Werewolf AI that outperforms GPT-4 with prompt engineering.
- We collect and release a comprehensive dataset¹ of 18800 real human Werewolf game sessions, which represents the largest dataset for social deduction games to date.

2 RELATED WORK

119 Enhance Reasoning in LLMs. Several approaches bypass the intricacies of prompt engineering. 120 For instance, LLM+P (Liu et al., 2023) employs an external planner to tackle long-horizon robot 121 planning challenges. A different approach (Zhang et al., 2023a) heuristically designs a low-level 122 planner to manage primitive control actions. The Retrieval-Augmented Generation (RAG) (Lewis 123 et al., 2020) merges pre-trained parametric memory generation models with non-parametric memory, aiming to enhance performance in knowledge-intensive tasks. Regarding the fine-tuning of LLMs, 124 Galactica (Taylor et al., 2022) is trained on a scientific dataset that emphasizes detailed reasoning 125 processes. WebGPT (Nakano et al., 2021) utilizes human feedback to fine-tune GPT-3, enabling it to 126 answer long-form questions within a textual web-browsing context. Toolformer (Schick et al., 2023) 127 fine-tunes LLMs for using external tools in a self-supervised manner with human demonstrations. 128 Swiftsage (Lin et al., 2024) employs GPT-4 with a small LM finetuned on the oracle agent's action 129 trajectories. DECKARD (Nottingham et al., 2023) trains an RL agent to execute subgoals planned by 130 LLMs in the game Minecraft. OpenAGI (Ge et al., 2023) implements RL from feedback in open-131 ended tasks to refine the LLM's planning strategy. Cicero (Bakhtin et al., 2022) fine-tunes LLMs to 132 generate dialogue controlled by a strategic reasoning module in the game Diplomacy, as shown in 133 Figure 1(a). Our approach diverges from Cicero in several key aspects: the predicted/intended actions 134 in Cicero (1) require both NLU and NLG involves a high-level and task-related reasoning beyond domain-agnostic NLP; (2) necessitate fine-tuning of LLMs; (3) are insufficient to convey complex 135 language dynamics in the Werewolf game (see Appendix B.1 and B.2). 136

137 AI for Social Deduction Games. DeepRole (Serrino et al., 2019) combines counterfactual regret 138 minimization (CFR) with deep value networks in the non-speech 5-player Avalon game. Hidden 139 Agenda (Kopparapu et al., 2022) presents a two-team, non-speech social deduction game in a 2D 140 environment. A system comprising three LLM-powered interfaces is created (Zhu et al., 2023) to aid gameplay in Dungeon Master. Regarding AI for Werewolf games, bootstrap aggregating and 141 weighted ensemble learning have been applied to refine voting strategies (Khan & Aranha, 2022). 142 Brandizzi et al. (2021) proposes an RL framework to analyze the influence of diverse communication 143 behaviors among agents. One Night Ultimate Werewolf (Eger & Martens, 2019) explores human 144 responses to various deliberation strategies. In the 5-player werewolf game, Wang & Kaneko (2018) 145 builds a deep-Q network to decide whom to trust or kill. Deep Wolf (Shibata et al., 2023) fine-tunes a 146 RoBERTa-like pretrained model with 48 game logs to construct a value network given the current 147 game state, human speeches, and candidate actions. The 7-player version is explored with RL and 148 LLMs in Xu et al. (2023b;a). Our approach differs from previous studies in two fundamental ways: 149 First, the Thinker separates LLMs from domain-specific reasoning. In contrast, LLMs in Xu et al. 150 (2023b) tackle most reasoning tasks and generate candidate outcomes from which an RL model 151 selects to mitigate biases, as illustrated in Figure 1(b). Second, by collecting and leveraging authentic human sessions and speech data, we aim for closer alignment with real-world scenarios and human 152 patterns beyond the few-shot capabilities of general-purpose LLMs. 153

154 155

156

3 Methods

We introduce an innovative framework that synergizes LLMs with an external Thinker module for
 reasoning and decision-making. To facilitate communication between the Thinker and LLMs, we
 propose a protocol utilizing language-based features and speech instructions. The framework is thus
 decomposed into three processing modules:

¹⁶¹

¹https://anonymous.4open.science/r/werewolf-1B74

Figure 2: The overall framework and its processing modules in the Werewolf implementation. The retrieval results from the Listener and the speech instructions for the Presenter are formatted in JSON-style for LLMs, while the language features generated by the Thinker are represented as numerical vectors.

- The *Listener* focuses specifically on domain-agnostic NLU tasks. It summarizes lengthy contexts, retrieves key information from natural language inputs, and transforms it into structured language features that the Thinker can interpret.
- The *Thinker* serves as the cognitive core of the framework. Utilizing language features provided by the Listener, it specializes in *System-2* reasoning tasks that require deep logical analysis and domain-specific knowledge. The Thinker produces policies such as planning and actions, and generates strategic instructions for the Presenter.
- The *Presenter* functions as the framework's articulator. Augmented by the strategic instructions from the Thinker, it generates coherent and contextualized language output that is logical, rational, consistent, free from hallucinations, and aligns with the current environment state.

It is important to note that the Listener and Presenter are separated functionally but can be instantiated by a single LLM. Therefore, the framework essentially comprises only an LLM and a Thinker module interacting with each other. To demonstrate the effectiveness of the framework, we apply it to the complex social deduction game Werewolf. The remainder of this section will detail the implementation, which necessitates deductive reasoning, speech understanding and generation, as illustrated in Figure 2.

3.1 DATA PREPARATION

- We collected data from the 9-player standard mode Werewolf game hosted on the Fanlang platform². 200 The specific rules of the game are detailed in Appendix C. We recorded real-time video in spectator mode for approximately 18800 game sessions, which equates to around 7000 hours of gameplay 202 and 6000 hours of audio. Furthermore, we enriched our dataset with a Werewolf domain-specific 203 corpus comprising nearly 1.4 million characters, derived from web-crawled game strategies and 204 OCR-processed Werewolf literature. Each recorded session includes both the game state data and the 205 audio of players' speeches. We captured exhaustive game details, such as historical skill usage and 206 voting results, by utilizing the Android automated testing framework³. The Paraformer (Gao et al., 207 2022) model was deployed for Automatic Speech Recognition (ASR) of human speech audio. To 208 improve recognition accuracy, especially for frequently used terms, we developed a list of hot words from the Werewolf corpus and applied context biasing methods (Zhao et al., 2019). Furthermore, we 209 annotated approximately 127 hours of Werewolf speech data and performed supervised fine-tuning 210 on the Paraformer model. The character error rate of ASR for Werewolf speeches was reduced from 211 4.5% to 3.7%. We refer to the dataset hereafter as *FanLang-9*, with a thorough analysis provided in 212 Appendix D. 213

216 3.2 LISTENER FOR DOMAIN-AGNOSTIC RETRIEVAL

The complexity of social deduction games stems from players concealing their identities. In the game of Werewolf, Werewolves disguise themselves as members of the "Good" faction through deceptive statements. Conversely, the "Good" faction strives to discern Werewolves by deducing from historical speeches and actions while providing rational and credible statements. This interplay significantly widens the gap between what players say and their true intentions (see Figure 5). The Listener aims to capture relevant insights from actual speeches without speculating on their hidden motives or truthfulness. To address these challenges, we introduce a dual-phase processing:

225 **Summary:** Human players' speeches on the Fanlang platform are characterized by an information 226 overload. This includes a tangled mix of context, lengthy and redundant content, and colloquial ramblings. Additionally, the speeches feature complex logic that encompasses quotations, rhetorical 227 questions, hypotheses, and empathetic thinking. Together, these elements result in a rich and intricate 228 web of discourse, the accumulation of historical speeches often exceeds 10k tokens (see Figure 9), 229 making it difficult for LLMs to directly retrieve key information from raw contexts. Inspired by the 230 Least-to-Most (LtM) prompting (Zhou et al., 2022), we prompt LLMs to generate a textual summary 231 not exceeding 200 words for each single speech, retaining only critical information that the speaker 232 intends to express. 233

Retrieval: Then we allow the same LLM to retrieve key information from the summary and generate a JSON-style reasoning result given 10 examples, which represents description of players' attributes in the speech. Finally, the result is tokenized and categorized into language features according to specific patterns in Table 8. For an *N*-player Werewolf game, we define *M* different attributes, which encompass various aspects of a player mentioned in the speech, e.g., identity guessing, historical or future skills and voting decisions. From the historical collection of all speeches \mathcal{H} , a player's single speech **S** may include descriptions of all the players in the game, the language feature can be represented as a matrix $\mathbf{F} \in \mathbb{Z}^{N \times M}$:

241 242

243

256

257

 $\mathbf{F} = [\mathbf{f}_1, \mathbf{f}_2, ..., \mathbf{f}_N]^T, \tag{1}$

where $\mathbf{f_n} = [f_{n1}, f_{n2}, ..., f_{nM}]^T$, n = 1, 2, ..., N and $f_{nm} \in \mathcal{V}_m, \forall n = 1, 2, ..., N$ and m = 1, 2, ..., N. Here \mathcal{V}_m signifies the set of the potential values that the *m*-th attribute can assume.

An example of summary and language feature (N = 9, M = 2) is illustrated in Figure 2. It is worth 246 noting that the dimensions of language features are significantly richer than the predicted/intended 247 actions outlined in Cicero (Bakhtin et al., 2022). Ablation studies (Appendix B.1 and B.2) demonstrate 248 that using actions as compressed representation of speeches leads to substantial information loss and 249 performance degradation in the Werewolf game. Aside from directly prompting LLMs to generate 250 language features, we also extract 260k speech instances from the FanLang-9 dataset, label the 251 speech-feature pairs with GPT-3.5, and fine-tune a ChatGLM-6B (Du et al., 2021) model, named as 252 WereLLM, to perform the same task for practical efficiency. The detailed prompts for summary and 253 retrieval, as well as the details for fine-tuning of the Listener, are provided in Appendix F.7 and F.6, 254 respectively. 255

3.3 THINKER FOR DOMAIN-SPECIFIC REASONING AND PLANNING

The Listener extracts key information from speech contents to generate language features. Then, the Thinker, utilizing the game state and all historical language features, deduces the underlying intentions and strategic implications of players' public speeches. For example, as shown in Figure 2, although Player 4 claims to be the Witch and accuses Player 9 of being a Werewolf, from Player 6's perspective, Player 4 might be a Werewolf disguising as the Witch, and Player 9 could more likely be the Hunter. Subsequently, it plans game-related actions and speech instructions.

The speech instruction $\mathbf{I} \in \mathbb{Z}^{N \times M}$ follows the same structure as the language feature in Equation 1, except that it is presented in JSON-style to align LLM input. This format is consistent with the retrieval results in the Listener. The generation of a speech instruction can be viewed as a multi-label classification problem and decomposed into multiple single-class classifications for each attribute f_{nm} . Therefore, we convert it into $N \times M$ discrete actions and apply the identical training algorithm used for game actions. The optimization of the Thinker comprises two phases: imitation learning and RL. For the imitation learning phase, we utilize human data and employ the Behavioral Cloning 270 (BC) (Torabi et al., 2018) loss as:

272

277 278 279

286

$$\mathcal{L}_{BC}(\theta) = -\mathbb{E}_{s,a\sim\mathcal{D}}[\log \pi_{\theta}(a|s)],$$
(2)

where \mathcal{D} denotes the dataset of human action *a* (or decomposed speech attribute f_{nm}), state *s*, and π_{θ} is the policy parameterized by θ . Since there are some gaps between the *FanLang-9* dataset and our simulation environment (see Appendix C.3), we further apply RL phase utilizing Proximal Policy Optimization (PPO) (Schulman et al., 2017) and a distributional training framework (Ye et al., 2020):

$$\mathcal{L}_{\mathrm{RL}}(\theta) = -\mathbb{E}_{s,a \sim \pi_{\theta'}} \left[\frac{\pi_{\theta}(a|s)}{\pi_{\theta'}(a|s)} A^{\pi_{\theta}}(s,a) \right],\tag{3}$$

where θ' is the parameters of an old policy, and $A^{\pi_{\theta}}(s, a)$ is the advantage with respect to policy π_{θ} , which is calculated by the Generalized Advantage Estimator (GAE) (Schulman et al., 2015). Additionally, we integrate an identity model designed to predict the identities of all players, which uncovers the Thinker's real deductions and may diverge from speech instructions it generates. We denote the loss function as $\mathcal{L}_{id}(\phi)$ with parameter ϕ , which is labeled by the game environment in a self-supervised manner. The overall training objective of the Thinker is formulated as:

$$\mathcal{L} = \mathcal{L}_{\mathrm{RL}}(\theta) + \alpha \mathcal{L}_{\mathrm{BC}}(\theta) + \beta \mathcal{L}_{\mathrm{id}}(\phi), \tag{4}$$

where α and β are weighting coefficients.

During the Thinker's training, we assume that the Presenter generates speech accurately based on 289 the speech instructions, and the Listener processes this speech and generate a language feature that 290 precisely matches the original speech instruction. This allows speech instructions to be directly 291 regarded as language features, thus enabling the Thinker to be optimized independently of the 292 Listener and Presenter. Given the game's asymmetric and adversarial nature, maintaining a balanced 293 win rate between the two opposing factions is crucial during training. To this end, we deploy distinct 294 models for the werewolf and the "Good" factions. We find that optimizing Werewolves' speech 295 instruction is much more challenging, as they need to mimic the "Good" faction's speech and master 296 the art of disguise and deception. To mitigate this, we draw inspiration from Generative Adversarial Networks (Goodfellow et al., 2014) and adjust the training iterations, $n_{\text{werewolf}} : n_{\text{goods}} = 5 : 1$. To 297 prevent actions and speech strategies from converging to a single pattern, we employ population-298 based training (Jaderberg et al., 2017) with a population size of 4. We also introduce fictitious 299 self-play (Heinrich et al., 2015), where in each game an average of 3 players employ the latest models, 300 while the remaining 6 players use models randomly selected from the most recent 500 checkpoints. 301 Further details on training pseudo-code, hyperparameters, reward shaping, and model structures are 302 in Appendix F.

303 304 305

3.4 PRESENTER FOR AUGMENTED SPEECH GENERATION

The generation of players' public speeches plays a crucial role in the Werewolf game, significantly impacting the outcome due to its strategic influence on actions and deductive reasoning of other players. The quality of the speech generation hinges on several critical aspects: (1) The strategy articulated within the speech should align with the player's role and the current state of the game. (2) Speeches need to adhere to the logical framework of the game, correlating with historical speeches and actions, making them sound and convincing. (3) Speeches are preferred to fit the stylistic environment of the Werewolf game. Detailed evaluation metrics can be found in Appendix F.2.

313 The Thinker module handles only the first aspect of speeches, providing a foundational strategic 314 instruction for the Presenter, such as the Witch's decision to report the previous night's rescue, as shown in Figure 2. Subsequently, the Presenter leverages NLG capabilities of LLMs to craft 315 a complete speech that incorporates the strategic instruction, relevant game state, and historical 316 speeches. The template for the prompt is provided in Appendix F.7. Additionally, as with the Listener, 317 we fine-tune the WereLLM to better align with human speech styles. The 260k speech-feature pairs 318 are inverted such that the language feature \mathbf{F} serves as the hindsight speech instruction \mathbf{I} , and the 319 actual speech S serves as output labels. 320

We have observed that LLMs often do not adhere to prompts, with even fine-tuned models sometimes
 producing hallucinations and inaccuracies. Taking inspiration from the Cicero (Bakhtin et al., 2022)
 approach, we introduce additional filtering steps. We use the Listener to perform further reasoning
 on the generated speech to produce a language feature, which we then compare for similarity to the

Figure 3: Voting and identity accuracy evaluating the deductive reasoning capabilities. The random baseline is calculated as the number of roles divided by the number of hidden players.

original speech instruction. For expressions detailing the speaker's own attributes, the filter demands an exact match. For expressions about others' attributes, the content indicated in the speech instruction must be consistent. For content not specified in the instruction, the filter allows the Presenter some flexibility, including minor hallucinations if they enhance the speech without detracting from its accuracy. The speech generation process repeats until it either meets the filter criteria or exceeds the maximum allowed attempts. Otherwise, a template-based speech is generated based on rules that consider the player's role, historical skills, and identity predictions.

4 EXPERIMENTS

We assess the performance of our framework by comparing it against several baselines and ablative variants. The models involved in the following experiments are as follows:

- **GPT-3.5/4**: GPT-3.5 and GPT-4 are directly applied to generate end-to-end action decisions and speeches. For GPT-3.5, we use the *gpt-35-turbo-16k* model, version 0613. For GPT-4, we apply the *gpt-4* model, version 1106-Preview. We prompt GPTs with game rules, explanations of typical game jargon, and comprehensive game information, including visible states, legal actions, and speech text converted by ASR. Detailed prompts are provided in Appendix F.7.
- GPT-3.5/4-LtM: This setting follows most aspects of the GPT-3.5/4 configuration, except that we allow GPTs to first summarize each speech after being given 11 examples (as shown in Table 16), and then we let the GPTs generate actions and speeches based on the game state and all speech summaries. The Thinker module is not applied, thus no language features are retrieved.
 - **GPT-3.5/4-T**: GPTs serve as the Listener and Presenter modules, while the Thinker module is integrated to generate actions and speech instructions. GPTs share the same prompts in setting **GPT-3.5/4-LtM**, except that additional speech instructions and identity predictions generated by the Thinker are added into the prompting of Presenter.
 - WereLLM-T: We replace GPTs with the WereLLM in both the Listener and Presenter as an efficient practical solution, while the Thinker remains the same as in GPT-3.5/4-T. It is worth noting that our framework allows for the use of fine-tuned LLMs but does not require them.

4.1 DEDUCTIVE REASONING

We begin by evaluating the models' deductive reasoning capabilities. Based on the current game state, the historical actions and speeches, models are required to identify special roles (Seer, Witch, and Hunter) and vote for the most likely werewolf, from the perspective of villagers in the voting round each day. Given that villagers have a minimal amount of game information and must engage extensively in deductive reasoning within the game, this task represents a stringent test of the models' understanding and comprehension. From the FanLang-9 dataset, we extract 300 games to serve as the test set, encompassing approximately 1200 evaluation instances. For the Thinker, we use its decision-making on actions for the werewolf voting task, and the identity model for identifying special roles. We assume that human players in the test set who are villagers would vote for the most likely werewolf. Thus, we list their voting choices as a reference, but their judgments regarding the identities of other players remain unknown.

Figure 4: Human preference score for generated speeches grouped by roles. 10 evaluators are tasked with ranking the 2000 speeches following the criteria detailed in Appendix F.2.

393 Figure 3 presents the accuracy results. In terms of voting Werewolves, human players have the highest accuracy and the Thinker is closest to human players. The Thinker outperforms direct 394 reasoning and prompting methods using GPTs in all the roles. LtM prompting enhances GPT-3.5's 395 performance, especially in identifying the Seer, indicating advantages in processing complex and 396 extensive speech contexts. However, the marginal gains of GPT-4-LtM over GPT-4 suggest that 397 the latter's enhanced capability to process extensive texts reduces its reliance on speech summaries. 398 In human gameplay, we observe that Seers and Witches often disclose their roles. This disclosure 399 aids GPTs in outperforming random baselines, while Hunters and Werewolves typically conceal 400 their roles, resulting in GPTs' performance aligning with random guessing. Notably, the accuracy of 401 GPTs generally declines over successive days, except for the Hunter, whereas the Thinker's accuracy 402 improves. This pattern suggests that although GPTs initially benefit from role disclosures on the first 403 day, they may be hindered by the extensive speeches in subsequent days.

390 391 392

4.2 THINKER-AUGMENTED SPEECH GENERATION

408 We then investigate the capabilities of various models in generating speeches. Utilizing the same 300 409 complete games as discussed in Section 4.1, we extract 400 speech sessions that span a diverse range 410 of roles, times of day, and speech types (first/second round speech, last words). Models are assigned 411 the task of generating speeches based on the current game state and all players' historical speeches, 412 with detailed prompts for GPTs available in Appendix F.7. Due to the demonstrated effectiveness of LtM prompting, subsequent experiments excluded GPTs that do not utilize LtM prompting. For 413 GPTs-T and WereLLM-T settings, speech instructions are derived from the Thinker and incorporated 414 into the prompts. We do not adopt the post filtering process for generated speeches in this experiment, 415 which yielded approximately 2000 speeches for five models. To assess the quality of the single-shot 416 generated speeches, we recruited 10 human evaluators, all well-versed in the Werewolf game. For 417 each session, generated speeches are presented in a randomized order to ensure that evaluators are 418 unaware of the model behind each speech. Evaluators are tasked with ranking the speeches and 419 identifying any clear legal errors, following the criteria detailed in Appendix F.2. 420

The evaluation results are shown in Figure 4. In terms of total scores, models augmented with Thinker 421 instructions outperformed their counterparts that relied solely on LtM prompting. Moreover, when 422 augmented with the Thinker, the 6B WereLLM surpasses GPT-4-LtM. When examining scores for 423 specific roles, the advantage of Thinker's contributions over GPT-3.5 appears somewhat marginal 424 for the Seer, whose speeches are relatively straightforward, needing only to report inspections from 425 the previous night. The assessment of villagers' speeches is inherently complex due to their limited 426 available information, which is reflected in the minimal rank score differences observed among the 427 models for this role. In contrast, differences on the rank score and illegal speak ratio are most obvious 428 for Werewolves. This disparity stems mainly from the low legality of werewolf speeches, which often inadvertently reveal their identity. Remarkably, GPT-3.5 appears to struggle with adhering to 429 instructions designed to avoid self-incrimination. In contrast, GPT-4 shows a more refined capability 430 to disguise its identity, especially when augmented by the Thinker's strategic instructions. An example 431 speech for the werewolf is presented in Figure 5.

4.3 ONLINE EVALUATION

Lastly, we conduct online evaluations to assess the overall performance of the models in a real-world 449 gameplay setting. Given that Werewolf is a multiplayer game with imperfect information, the skill 450 level of the participants can significantly influence the evaluation results. Therefore, we devise three 451 combinations of models, with models being randomly and repeatedly selected to simulate 9-player 452 games. We conduct approximately 600 rounds for each combination to ensure robust testing results. 453 Given the inherent randomness of outcomes in the game, we also calculate the Behavior Score, a 454 typical metric used in Werewolf competitions⁴ to evaluate behavior of players, e.g., a Villager voting 455 for a werewolf, a Hunter shooting a werewolf, a comprehensive breakdown is provided in Table 9.

456 The results summarized in Table 1 reveal that integrating the Thinker module significantly boosts 457 the win rates of both GPT-3.5 and GPT-4 across all three model combinations. The performance 458 of the WereLLM-T model closely aligns with that of GPT-4-T. In terms of Behavior Score, the 459 Thinker contributes substantial improvements across all roles for GPT-3.5. For GPT-4, notable 460 benefits are observed particularly for the Witch and Hunter roles. The Behavior Score metric assigns 461 significant weight to the witch's poisoning and the hunter's shooting decisions, which correlates with 462 the Thinker's ability to enhance werewolf detection and subsequently improve these scores. Another 463 notable finding is that the combination involving GPT-4 and WereLLM-T models yields the highest win rate for Werewolves. This outcome primarily stems from the conservative nature of GPT-4-LtM 464 in role identification, which leads it to be more cautious in voting and skill usage as the "Good" 465 faction. In Appendix B.2, we also include an ablation of our framework with Cicero (Bakhtin et al., 466 2022) and LLM prompting-related approach Xu et al. (2023b), demonstrating that our method still 467 maintains a significant advantage in terms of win rate. 468

Table 2: Online evaluation win rates with 1 human and 8AIs.

Method	Total	Goods	Werewolves
GPT-4-T	46.9%	37.3%	65.0%
WereLLM-T	45.3%	36.0%	62.6%
Human	40.5%	35.3%	59.4%

476 Furthermore, to evaluate AI performance against human strategy, we incorporated 13 human players 477 into the evaluation. We find that the issue of werewolf identity exposure, as illustrated in Figure 4, 478 significantly impedes the game experience for human players. As a result, human evaluators play 479 alongside four instances each of GPT-4-T and WereLLM-T models across 200 game rounds, and the 480 post-filtering process for generated speeches is adopted in this setting. In Table 2, human players 481 exhibit no significant win rate advantage, suggesting that the AI's speeches and actions do not exhibit exploitable weaknesses. Moreover, when compared with the results in Table 1, we observe a relative 482 decrease in the Werewolves' win rate in games involving human players, highlighting the ongoing 483 challenges related to identity concealment. Although AI-managed Werewolves might convincingly 484

485

469

⁴https://langrensha.163.com/20230313/31014_1077578.html

deceive other AI players, human players often find them suspicious. A typical example is that
 Werewolves tend to act in groups, such as unanimously voting for a certain player.

5 DISCUSSION AND LIMITATION

Transfer to other tasks: We use language features and speech instructions in our framework to integrate LLMs and external reasoning models. The communication format may not be directly transferable to other tasks or domains, with its effectiveness depending on the richness of these features and instructions. Future work aims to develop more generalized and flexible methods, such as using implicit hidden vectors in a data-driven manner, potentially offering better transferability at the expense of interpretability and controllability.

Evaluation of 8 humans with 1 AI: Our evaluations primarily involved games featuring either AI
 vs AI or one human player competing against multiple AIs. Evaluating an AI in a majority-human
 player setting presents challenges due to the highly interactive nature of the game and the variability in human players' speech strategies and behaviors.

Interpretability: While our framework improves the reasoning capabilities of LLMs, the reasoning processes in the Thinker module may not be easily interpretable to humans. We explicitly introduce the identity prediction task to reveal how the Thinker thinks of other players. Future work could explore methods for further improving the interpretability and transparency of our framework.

6 CONCLUSION

509 In this paper, we introduced a novel framework that integrates LLMs with an external Thinker module, aiming to enhance the reasoning capabilities of LLM-based agents. This approach is inspired by the 510 dual-process theory and separates reasoning tasks into two systems: System-1, handled by LLMs, and 511 System-2, handled by the Thinker. We showcased our approach in the context of the Werewolf game, 512 a complex social deduction game requiring language processing, intuitive thinking, and strategic 513 planning. Our results show that our framework can significantly improve the performance of LLMs 514 and achieve better alignment with real-world scenarios and human preferences. Additionally, we 515 fine-tune a 6B WereLLM to surpass GPT-4 when integrated with the Thinker. Furthermore, this paper 516 contributes the largest dataset for social deduction games to date, aiming to accelerate advancements 517 in this field.

775									
776	Regarding related works in Figure 1, we detail the ev	alving process of our framework as follows							
777	Regarding related works in Figure 1, we detail the ev	orving process of our framework as follows.							
778									
779	A.1 MOTIVATION								
780									
781	In the game of werewolf, there is a significant gap bet	tween what a player says and what the player is							
782	actually thinking. Consider the scenario depicted in	Figure 5, where Player 3, a werewolf, publicly							
783	states:								
784	"I am the Seer, and I have checked Player 9, who is a good person. I suspect that Player 8 is a werewolf."								
785									
786									
787	of Player 3 (System 2) might be as follows:								
788	of Player 5 (System-2) might be as follows:								
789	"Players 6 and 7 are my fellow Werewolves (as per t	the game rules, Werewolves know each other's							
790	identities), and Player 8 claims to be the Seer and has accused Player 7, who is on my team. Therefore,								
791	Player 8 is likely the real Seer. By also pretending to be the Seer and verifying Player 9 as a good								
792	role, I can create a conflict with Player 8 in the eyes	of the villagers."							
793									
794	Δ 2 IIM PROMOTING METHODS								
795	A.2 LEWI KOWFILNO WIEIHODS								
796	We identified several shortcomings when examining t	he performance of LIM with twnical prompt or							
797	mechanism engineering methods. The shortcomings	can be categorized into two main areas.							
798	meenanism engineering methods. The shortcomings	can be categorized into two main areas.							
799	Over-trust : LLMs exhibited a tendency to over-trust	other players' self-declared identities, particu-							
800	larly when players claimed to be Seer or Witch roles.	Furthermore, when the LLM assumed the role							
801	of a werewolf itself, it was prone to inadvertently exp	osing its own identity, which is demonstrated in							
802	Figure 4 and Figure 5.								
803	Strategic Deficiencies: LLMs showed a lack of family	liarity with the common strategies employed in							
804	the Werewolf game. For instance, they failed to gras	p tactics such as Werewolves pretending to be							
805	Seers to mislead other players, Werewolves accusing	their teammates to gain the trust of the "Good"							
806	players, or Villagers pretending to be Seers to protect	t the real Seer from being killed, etc. These are							
807	conventional tactics used by experienced human play	ers to navigate the complex social dynamics of							
808	Werewolf, which involve deception, trust, and betray	al.							

To delve deep into the reasoning process of LLMs, we dissected the process from listening to speaking in the game into four stages, as shown in Figure 1 and investigate issues one by one:

- (1) **NLU**: It is assigned as the Listener's goal in Figure 2, is to interpret speeches and extract their explicit meanings. LLMs show proficiency in this area.
- (2) **Deductive reasoning**: LLMs underperform in role identification, often over-trust other players' self-declared identities, as tested in Section 4.1. Then the deductive reasoning is limited to information extraction.
- (3) **Speech strategic planning**: LLMs struggle to outline a comprehensive speech plan, especially when assuming the role of a Werewolf. They frequently risk exposing themselves or their allies (see Figure 5), lacking an understanding of conventional Werewolf game speech strategies.
 - (4) **NLG**: Although LLMs are unfamiliar with conventional speech strategies, we find that they can generate coherent and convincing speeches once prompted with basic instructions, such as "You should pretend to be the Seer and accuse Player 3 of being a werewolf".

814

815

816

817

818

819

A.3 TRANSITION TO THE THINKER MODULE

824 The primary reason for the above shortcomings is that LLMs are not trained on Werewolf-specific 825 knowledge corpus and data. Although it is possible to prompt LLMs with common game termi-826 nologies through in-context learning, strategic experiences are challenging to encapsulate in text 827 prompts. To address the deficiencies in deductive reasoning and speech strategic planning, we 828 consider developing a trainable Thinker model to handle these aspects separately from the LLMs. 829 The Thinker module is optimized through imitation learning and reinforcement learning, using human 830 game data as a foundation. It is designed to complement the LLMs, then the latter are responsible for 831 intuitive, domain-agnostic System-1 reasoning tasks.

832 833

834

- A.4 COMPARISON WITH CICERO
- ⁸³⁵ In brief, the differences between our approach and Cicero are as follows:

836 Different Roles for NLU and NLG: In Cicero's approach, both NLU and NLG involve a high-level 837 logical reasoning process: NLU directly outputs action predictions, which is actually a complex 838 reasoning process that goes beyond natural language processing. Similarly, NLG takes intended 839 actions as control signals, but it still requires a comprehensive consideration of the game state, 840 historical speeches, and higher-level reasoning to generate reasonable dialogue/speech that matches 841 the intended action. In contrast, in our Werewolf game approach, the Listener (NLU) is only 842 responsible for extracting key information from speeches and does not infer the truthfulness of the 843 speeches or the underlying intentions. Similarly, NLG expands speech instructions, which are outlines 844 of speeches, into full statements in context, requiring less domain-specific reasoning.

845 The Connection between LLMs and Policy: In Cicero's approach, the connection between LLMs 846 and policy is made only through action prediction and intended action, which is non-language-based. 847 In the Werewolf game scenario, we found that using actions alone is not sufficient, as the Listener 848 causes significant information loss. Due to the complexity of Werewolf speeches, intended actions 849 also struggle to describe and control speech generation. This leads to a noticeable disadvantage for Cicero's approach in the ablation study presented in Table 3 and Table 4. To address this, we propose 850 a language-based feature and speech instruction that include complex verbal information, which can 851 effectively summarize player speeches and control the speech generation process. 852

Different Training Modes: Due to Cicero's method involving NLU and NLG in task-specific
high-level reasoning processes, it is necessary to fine-tune both NLU and NLG. In our approach, by
defining explicit language-based connections and isolating domain-specific complex reasoning from
LLMs with the Thinker, we can avoid the fine-tuning of NLU and NLG.

857 858

859

A.5 COMPARISON WITH OTHER DUAL-SYSTEM METHODS

Our work mainly differs in that we utilize an RL model for system-2 reasoning (deductive reasoning and strategic planning in the Werewolf game), while the related work primarily relies on LLMs for complex, domain-specific system-2 reasoning, as shown in Figure 6. We believe that employing an RL policy model for system-2 reasoning is a viable choice in complex decision scenarios (for example, GPT4 + AlphaGo) and specific domain contexts where LLM pre-training does not include

Time	Tatal	Night skills			Day actions	
Time	Total	Werewolves	Witch	Seer	Hunter	Vote
Day1	37.0% [422/1142]	13.3% [40/300]	97.0% [97/100]	12.0% [12/100]	0.0%	42.8% [273/638]
Day2	30.3% [268/884]	17.0% [51/300]	20.6% [20/97]	18.4% [14/76]	10.0% [1/10]	45.4% [182/401]
Day3+	36.6% [128/350]	34.4% [67/195]	30.0% [3/10]	22.7% [5/22]	33.3% [1/3]	43.3% [52/120]

Table 3: Accuracy of predicting future actions.

domain knowledge. In such cases, LLMs primarily function in the role of NLP, corresponding to the Listener and Presenter in our text.

Mathad	System1		System2			
Wethod	Model	Function	Function Alignment		Function	Alignment
Swiftsage	Small LM	Generate actions	Finetune	LLM (GPT4)	subgoal planning and grounding	Prompting
DECKARD	Policy model	Execute subgoals, action and control	RL	LLM	Decompose and subgoals	Prompting
Ours	LLM	NLP related, explainability	Prompting or SFT	Policy model	deductive reasoning and strategic planning	RL

Figure 6: Comparison of system components and functionalities.

B ADDITIONAL RESULTS AND ABLATION STUDIES

B.1 PREDICTING ACTION AS LANGUAGE FEATURES

We study the approach used by Cicero (Bakhtin et al., 2022), utilizing the prediction of players' future actions as a feature representation of speeches and as a control variable for the speech generation. Aside from the example illustrated in Figure 2, we additionally conduct experiments by feeding the model with complete game states and historical speeches to predict players' future actions. We finetune the WereLLM model using data from the *FanLang-9* dataset and then test the action prediction accuracy on a set of 100 test games.

The results are shown in Table 3. Overall, the action prediction accuracies for three days do not exceed 40%. Notably, the Witch conventionally saves the player killed by Werewolves on the first day, resulting in a high accuracy. One point of particular interest is the accuracy of voting predictions, which consistently remained just over 40% as the days progressed. In the game of Werewolf, the speaking order plays a crucial role; players who speak earlier often mention multiple potential voting targets. By listening to subsequent speeches, players can make informed decisions or adjustments regarding their final vote. This aspect of the game dynamics makes the implementation of Cicero's method challenging in the context of Werewolf.

B.2 COMPARISON WITH OTHER APPROACHES

In this section, we compare the performance of our proposed method, a Cicero-like baseline variant, and the approach described in Xu et al. (2023b). To ensure a rigorous experimental comparison, we adapted the implementations of the comparative methods to account for differences in implementation details, thereby enhancing the persuasiveness of our results. Below we outline the configurations for each method:

Our Method: We employ the **GPT-4-T** setting, wherein the Listener and Presenter modules utilize GPT-4, and the Thinker module is powered by the RL-optimized model.

Variant of Cicero: For this baseline, we reduce the language feature and speech instruction dimensions to a single dimension, representing the future action of a speaking player. As experimental findings in Appendix B.1 indicated that fine-tuning WereLLM yielded low action prediction accuracy, we directly use GPT-4 to generate language features and speech instructions in the Listener and Presenter. The Thinker module employs an RL model for training, with its language feature and speech instruction also condensed to one dimension. All other configurations are consistent with GPT-4-T.

925 Variant of Xu et al. (2023b): Diverging from the original implementation, we modify the approach 926 to have GPT-4 generate three speech instruction candidates instead of directly producing speak 927 candidates. The Thinker then selects one speech instruction, which is subsequently used by the 928 GPT-4 Presenter to generate speech. Due to the discrepancy between LLM inference and Thinker RL sampling speeds, the Thinker is restricted to using offline RL. For offline RL data construction, we 929 extracted 1000 game sessions from the FanLang-9 dataset. For each instance of speaking, we allow 930 GPT to generate five speech instruction candidates. During offline RL training, we randomly selected 931 two of the five GPT-generated candidates and combined them with the human speech instruction to 932 form three speech instruction candidates, yielding 10 possibilities for data augmentation. The Thinker 933 makes its selection, with its inputs including the game state, language features as in GPT-4-T, and the 934 three speech instruction candidates. The actual selection for BC is the human speech instruction. 935

To summarize, the primary distinction between GPT-4-T and the Cicero variant lies in the modification of the dimensions and meanings for language feature and speech instruction. And the Thinker in the variant of Xu et al. (2023b) no longer generates speech instructions; instead, it directly selects from generated candidates. The evaluation results are shown in Table 4. Our GPT-4-T method surpasses the variant of Xu et al. (2023b) in performance, and significantly outperforms the Cicero variant, highlighting the advantages of external Thinker module in terms of reasoning and strategic communication within the Werewolf game.

Table 4: Win rate comparison of our method with other approaches.

Method	Total	Goods	Werewolves
Variant of Cicero (Bakhtin et al., 2022)	34.4%	28.5%	47.9%
Variant of Xu et al. (2023b)	47.8%	37.4%	67.7%
Ours (GPT-4-T)	53.5 %	41.6 %	75.2 %

B.3 COMPARISON WITH OTHER PROMPTING APPROACHES

We compare our method with more complex prompting approaches. The experiment includes three configurations:

- **GPT-4-LtM**: The same as in the main text, except that we switch to the *gpt4-turbo-2024-04-09* model.
- **GPT-4-T**: The same as in the main text, except that we switch to the *gpt4-turbo-2024-04-09* model. It is worth noting that the LtM prompting is applied in this setting.
- **GPT-4-LtM-ReAct**: The same as the **GPT-4-LtM** configuration, except that we additionally apply ReAct (Yao et al., 2022) prompting. Each time it is the player's turn, we allow the GPT to analyze and guess the role of other players and their future skills and voting decisions, and buffer all the historical guessing and thinking as additional information in the prompts.

966 967

943 944

956

957 958

959

960

961

962 963

964

965

We conduct 500 rounds for the combination to ensure robust testing results. The results are shown
in Table 5. As can be seen, compared to GPT-4-LtM-ReAct and GPT-4-LtM, the additional, more
complex ReAct prompting provides limited improvement (1%) in GPT's capabilities. GPT-4-T shows
a significant improvement over GPT-4-LtM-ReAct, even though it only uses LtM prompting. This
indicates that the Thinker module plays a key role in the reasoning of the Werewolf game.

Tuble .	Tuble 5. Win Tube comparison of our method with other prompting uppr						
	Method	Total	Goods	Werewolves			
-	GPT-4-LtM	41.2%	28.2% 28.5%	68.8%			
	GPT-4-T	42.3 <i>%</i> 45.7%	30.9 %	74.0 %			

Table 5: Win rate comparison of our method with other prompting approaches.

978 979 980

981

972

B.4 TRANSFER TO 6-PLAYER WEREWOLF GAME

To demonstrate the generalizability of our framework, we transfer the Thinker module trained on a 983 9-player Werewolf game to a 6-player Werewolf game. The 6-player Werewolf game consists of 2 villagers, 2 werewolves, a Seer, and a Savior. Each night, the Savior can choose to protect a player 985 from being killed by the werewolves, but the protection cannot be given to the same player on two 986 consecutive nights. The Savior in the 6-player game is similar to the Witch in the 9-player game, 987 except without the poison and with an unlimited supply of antidotes.

The Thinker module is initially trained by RL and BC in the 9-player game, then fine-tuned in the 6-player game mode with RL. Since speeches in the *FanLang-9* dataset (9-player) might violate the rules of the 6-player game, e.g., "Player 9 is Seer", "Players 2, 5, 6 might be werewolves", we cannot easily fine-tune the WereLLM and transfer it to the 6-player game. Therefore, we test the combination of GPT-4, GPT-4-LtM, and GPT-4-T. The WereLLM-T setting is not included in this ablation. The details of these three models are the same as in the main text, except that we switch the GPT behind these three settings to the *gpt4-turbo-2024-04-09* model.

The results are shown in Table 6. The experimental conclusions are quite similar to those in Table 1.
Compared to GPT-4-LtM and GPT-4, the LtM prompting provides limited improvement in GPT's capabilities. GPT-4-T shows significant improvement over GPT-4-LtM.

998 999 1000

1001 1002 Table 6: Win rate of Thinker module transferred in the 6-player Werewolf game.

Method	Total	Goods	Werewolves
GPT-4	48.7%	50.4%	45.3%
GPT-4-LtM	50.1%	51.4%	47.3%
GPT-4-T	53.1%	53.7 %	51.8 %

B.5 TRAINING CURVE

The population-based RL training of different agents is illustrated in Figure 7.

1011 C GAME RULES

1012

We follow the 9-player standard mode Werewolf game rules on the Fanlang platform. The rules are outlined as follows.

1015

1023

1024

1025

1016 C.1 OBJECTIVES

The game is divided into two factions: the "Good" faction, which includes Villagers and special roles, and the "Werewolf" faction. Additionally, there is a Moderator who is responsible for managing the game and ensuring the rules are followed. The goal for the "Good" faction is to identify and eliminate all Werewolves, while the Werewolves aim to kill or exile all Villagers and special roles. The game ends when any of the following conditions are met:

- All Villagers are out of the game (Werewolves win)
- All special roles are out of the game (Werewolves win)
 - All Werewolves are out of the game ("Good" faction win)

Figure 7: Detailed training curves for different agents during RL training. The x-axis represents the training steps (k), and the y-axis represents the probability. The horizontal line in each subplot corresponds to the probability observed in human data. "Werewolf -> Seer" represents that a Werewolf claims to be the Seer in the speech.

1060 1061

C.2 ROLES

1062

The game comprises 3 Villagers, 3 Werewolves, and 3 special roles (Seer, Witch, and Hunter). The identities of the players are hidden from each other, even after being eliminated from the game.

Werewolves: Werewolves are aware of each other's identities. At night, they decide to kill a living player, which may include one of their own. The majority of the Werewolves' choice will be the final kill target. If there is a tie, a random player in the tie is killed. Werewolves can commit suicide during the speech sessions, which will reveal their identity, and the game immediately proceeds to the night phase, skipping the remaining daytime processes such as speeches and voting.

1071 Villagers: Villagers have no special abilities. They must determine other players' identities based on
 1072 their speeches and vote to exile potential Werewolves.

Seer: The Seer can verify a player's faction each night (either Werewolf or "Good"), but cannot discern their specific role. The Seer cannot verify himself or any player who has already been verified.

1075
1076
1076
1077
1078
Witch: The Witch possesses an antidote and a poison. The antidote can save a player killed by Werewolves at night, and the poison can kill a player. The Witch cannot use both potions in the same night and can only save herself on the first night.

Hunter: When the Hunter is killed by Werewolves at night or voted out during the day, he can shoot a player. However, the Hunter cannot use his ability when poisoned by the Witch.

1080	C.3 GAME TASK FLOW
1082	The game proceeds in a night-day cycle until the victory conditions are met.
1083	The night tasks flow:
1084	
1085	(1) Werewolves decide to kill a player. In our simulation of the game environment, we have simplified
1087	the discussion into a three-round voting process. During voting, werewolf players can see
1088	(2) The Witch uses her ability
1089	(3) The Seer uses his ability.
1090	
1091	The daytime tasks flow:
1092	(1) The Moderator announces the deaths from last night but does not reveal the causes of death.
1093	(2) Deceased players give their last words (only for the first day).
1094	(3) If deceased players have additional abilities, they may choose to use them.
1095	(4) First round of speeches. The speech sequence is determined by the following rules: (a) if no
1096	player died last night, randomly select an initial speaker and randomly decide a clockwise or
1097	counterclockwise speaking order. (b) A deceased player is randomly selected, and the speaking
1098	order starts clockwise or counterclockwise from nim. Players cannot interrupt others during their speeches
11099	(5) First round of voting. Each player votes for a single player to exile from the game. Other players'
1101	voting choices remain hidden until the voting session ends.
1102	(6) Second round of speeches. If there is a tie in the first round of voting, the tied players give
1103	their second speeches; otherwise, the process moves on to task (8) The first speaker, selected
1104	randomly from the tied players, initiates the sequence, which could proceed either clockwise or
1105	Counterclockwise.
1106	(7) Second round of voting. If there is suit a the after the second vote, the game moves of to the fext night and no player is exiled
1107	(8) The exiled player gives his last words.
1108	(9) If exiled players have additional abilities, they may choose to use them.
1109	
1110 1111	D ANALYSIS OF THE FanLang-9 DATASET
1112	The <i>FanLang-9</i> dataset consists of 18800 recordings and 260K speech instances, with an average
1113	speech length of 500 characters. Specifically, the following characteristics underscore the unique
1114	nature of the dataset:
1116	
1117	D.1 Speech Duration and Length
1118	Figure 8 (a) demonstrates significant variations in speech duration among different roles, with an
1119	average of approximately 90 seconds each. The Seer's inspection information at night forms the
1120	core and fundamental logical basis of the game. Therefore, it is the Seer's duty to share inspection
1121	information, provide persuasive speeches, and lead discussions during the speech phase, resulting
1122	identify themselves and predict the roles of other players, necessitating detailed and logical analysis.
1124	In Figure 8 (b) the dataset shows the shortest taken length among Werewolves, which is not correlated
1125	with their speaking time. This suggests that Werewolves' speeches are relatively concise, which may
1126	stem from the complexity of deception that requires more time to strategize. We further illustrate the
1127	distribution of token length in a single speech in Figure 9.
1128	
1129	D.2 TOKENIZATION AND CATEGORIZATION OF SPEECHES
1130	
1131	The reasoning result of a speech produced by the Listener is formatted in JSON style, containing pairs of player IDe with their attributes. The result turically includes phrases and word groups containing

of player IDs with their attributes. The result typically includes phrases and word groups containing multiple attributes, probabilities, and irrelevant information, e.g., "seems to be a werewolf: [3, 6]", "cannot hear clearly: [8]". We then tokenize and categorize the result into related identities and

Figure 8: Speech duration and token length categorized by roles in the *FanLang-9* dataset.

actions, along with their probabilities, as shown in Table 8. The final language features account for
96.09% of the *FanLang-9* dataset, capturing the majority of the information expressed by speakers in
the Werewolf game.

Figure 9: Distribution of speech token length.

1167 D.3 VOTING PREFERENCE

We analyze how human players tend to vote in the perspective of different roles in Figure 10 (a). As for voting Werewolves, the Seer has the highest accuracy of identifying Werewolves due to his inspection ability, while Werewolves vote for their teammates with a probability of 15.7%, aiming to disguise themselves as the "Good" faction. The other roles have a 50% chance of voting for Werewolves, since they lack additional information beyond the game state and historical speeches. As for voting from Werewolves, the most prioritized target are the Villagers (28.6%), since they have the least amount of information and are easier to be incriminated as Werewolves. The second prioritized target is the Seer (28.1%), since the Seer can inspect players' identities, it is crucial to remove him out of the game as soon as possible.

1179 D.4 FINAL STATE OF THE ROLES

In Figure 10 (b), we present the final states of roles in the end of the game, categorized as *Survived*, *Shot* by the Hunter, *Poisoned* by the Witch, *Killed* by Werewolves, *Exiled* after the Voting stage, and Werewolves committed *Suicide*. Notably, the Witch has the highest likelihood of being killed by Werewolves at night (55.3%), with the Seer following at 32.5%. Werewolves commit suicide with a probability of 17.3%, and are killed by their teammates at night with a probability of 2.5%. During the daytime voting, Werewolves are the most frequently exiled role, indicating their challenges in providing deceptive statements, while the Witch has the lowest probability, reflecting their effectiveness in gaining trust through speeches.

Figure 10: (a) Voting probability distributions for players with different identities across all voting sessions; (b) Final survival status and causes of death probabilities for players at the end of the game.

1207 D.5 WIN RATE

1209 Table 7 illustrates that in human gameplay, the win rates for the Good and Werewolf factions are 1210 closely matched.

Table 7: Win rate in the FanLang-9 dataset.

Camp	Win number	Win rate
Goods	9293	49.31%
Werewelf	9554	50.69%

Table 8: Tokenization and categorization of speeches on the FanLang-9 dataset.

Tokenized attributes	Is	Might be	Is not	Might not be	Is not sure	Ratio	Accumulatio
Werewolf	178423	27297	516	313	15	26.55%	26.55%
Good (the good faction)	83071	622	85	73	10	10.77%	37.32%
Vote	68853	87	81	1	3	8.87%	46.19%
Seer	60339	114	111	321	8	7.82%	54.01%
Witch	35408	42	29	8	3	4.56%	58.57%
Gold Water (checked Good)	34727	8	8	1	/	4.46%	63.03%
Check (Seer's inspection)	26027	17	17	/	/	3.35%	66.38%
Poison	21897	82	9	1	/	2.83%	69.21%
Villager	21611	28	19	10	1	2.78%	71.99%
Werewolves' target	19481	17	12	/	1	2.51%	74.50%
Hunter	17603	26	70	5	2	2.28%	76.78%
Silver Water (saved)	14016	3	5	1	2	1.80%	78.58%
Suicide	3826	4	1	/	1	0.49%	79.07%
Uncertain Identity	/	/	/	/	2937	0.38%	79.45%
Shoot	1100	2	2	/	/	0.14%	79.59%
Save (by the Witch)	1065	/	/	/	/	0.14%	79.73%
Abstain voting	683	3	1	/	/	0.09%	79.82%
Special Role	273	4	/	/	/	0.04%	79.86%
Irrelevant Information	126279	/	/	/	/	16.23%	96.09%
Unprocessed	30476	/	/	/	/	3.91%	100.00%

1242 E ETHICAL CONSIDERATIONS

1243 1244

With the integration of LLMs into complex reasoning tasks, as demonstrated in social deduction games like Werewolf, we are witnessing the emergence of AI agents. These agents not only mimic humanlike reasoning but also engage in communications that could inherently be considered deceptive. While these developments showcase the potential of AI to understand and navigate intricate human interactions, they also raise important ethical and societal considerations that must be addressed. To address these ethical and societal challenges, we propose several mitigation strategies:

Transparent Communication and Monitoring: Our framework ensures transparency through explicit structured information at every stage of the AI's decision-making process, from listening and reasoning to speech generation. To enhance this transparency, we propose implementing real-time transparency logs that capture and display the reasoning paths, identity predictions, and speech instructions generated by the AI. By having a complete audit trail, we can monitor the AI's decision processes, ensure adherence to ethical guidelines, and trace any unintended actions back to their source.

1257 Control and Filtering Mechanisms: Our speech instructions are enriched with contextual infor-1258 mation specific to the Werewolf game, allowing for robust control over the fine-tuned LLM. To 1259 further mitigate potential negative impacts, we propose implementing dynamic contextual guardrails. 1260 These guardrails will utilize our existing filtering mechanism (as outlined in Section 3.4) to not 1261 only match generated speech with instructions but also to check against a set of ethical and societal norms. If the AI's output is flagged as potentially harmful or deceptive beyond the game's scope, 1262 it will be withheld and replaced with a template response. This additional layer of control will act 1263 as a safeguard against the misuse of AI in generating deceptive or manipulative content outside the 1264 intended gaming environment. 1265

1270

¹²⁶⁹ F.1 DETAILS FOR HUMAN EVALUATORS

We recruited 13 human players to participate in the online evaluation of 1 human and 8AIs in 1271 Table 2. And 10 of them further participated in the evaluation of speech generation in Figure 4. 1272 The participants are selected from a board game association consisting of over 60 people, and the 1273 association regularly hosts offline Werewolf games. The evaluators are not paid for the evaluation 1274 and are required to be familiar with the rule of 9-player Werewolf games and have participated in 1275 at least 20 online/offline Werewolf games. Due to the multiple different versions of the Werewolf 1276 game, before the evaluation, we provided all evaluators with a detailed demonstration based on data 1277 analysis from 18 000 FanLang-9 game sessions, including the probabilities of different strategies for 1278 different roles, and required them to watch at least 10 game recordings from FanLang-9.

1279 1280

1281

1285

1286

1293

- F.2 CRITERIA FOR EVALUATING SPEECH GENERATION
- ¹²⁸² The human evaluation requirements for speech generation are as follows.
- **Legality:** Absence of obvious logical errors and statements that conflict with the game rules, such as:
 - "I am a Werewolf."
 - "I am the Seer, and I poisoned Player 5 last night."
- 1287 Tail the Seel, and I poisoned Player 5 last hight.
 * "Player 3 is a good person; I suggest voting for him."
- "I suggest voting for myself."
- "Player 8 is a Werewolf, he was voted out and took Player 6." (Incorrect: Player 8, as the hunter, publicly shot Player 6).
 - "I suggest voting for Player 8." (Incorrect: Player 8 has already been voted out).
- 1294 **Reasonableness:** of the speeches, such as:
 - The Seer correctly reports his inspection last night.

Werewolves reasonably disguise their identities by employing various strategies, such as pretending to be the Seer, making aggressive claims, and betraying their teammates.

• Villagers make reasonable guesses about the Good faction and Werewolves.

• Note: the correctness of guessing other players' identities is not part of the evaluation criteria.

1301 **Other:** factors unrelated to key information:

• Language style, colloquial expression, game jargon.

• Presence of verbose or redundant statements, such as greetings or defending the village community.

The evaluation criteria are in descending order of priority. For example, if model A has no obvious logical errors but its speech is not very reasonable, and model B has obvious logical errors, then A is better than B. When ranking the five samples, mark any with obvious logical errors as -1; these do not require further ranking. For example, if models A and B have obvious errors, the annotation result could be: A : -1, B : -1, C : 1, D : 2, E : 3, where 1 represents the best and 5 represents the worst. Apart from marking illegal statements as -1, tied rankings are not allowed.

Table 9: Behavior scores applied in the 9-player werewolf game.

Role	Description	Score
Seer	If a werewolf is exiled in the first day For giving up the inspection at night	$+0.5 \\ -0.5$
Witch	For poisoning a werewolf For poisoning a good player	$+1.0 \\ -1.0$
Hunter	For shooting a werewolf For shooting a good player	$+1.0 \\ -1.0$
Good roles except the Seer	For voting for a werewolf For voting for a good player	$+0.5 \\ -0.5$

1324 1325 1326

1327 F.3 MODEL STRUCTURE OF THE THINKER

The Thinker network's architecture is designed to capture the intricacies of gameplay from the current
 player's perspective. It encompasses speeches, actions, and game status information for all nine
 involved players, including the player itself. We employ a shared-parameter feature encoding network
 to process the data for each of the nine players individually.

1333 For the *i*-th player, up to 10 language features F are stored. These language features are enriched 1334 with headers indicating the time-tag, type, and order of the speeches. Subsequently, these annotated 1335 language features are processed through another shared-parameter speech feature encoding network, which consists of a three-layer multilayer perceptron (MLP) network (181-256-256). After processing 1336 the ten pieces of features, a *reduce_mean* operation is applied to the outputs to synthesize the overall 1337 speech embedding for the player e_i^{speech} . This synthesized speech embedding is then combined with 1338 additional game state information such as the player's actions, status, and other relevant data. The 1339 aggregated data is fed through a feature encoding network (again, a three-layer MLP of 1019-512-512) 1340 to generate the feature embedding for the *i*-th player e_i . 1341

1342 In the final step, the feature embeddings of all nine players $e_1, e_2, ..., e_9$ are subjected to a *re-*1343 *duce_mean* operation to create a collective feature encoding. This comprehensive encoding is then 1344 passed through an all-player feature encoding network (a three-layer MLP of 523-512-512) to con-1345 struct the corresponding action decision, identity prediction headers, as well as speech instructions.

1346

1348

1347 F.4 REWARD SHAPING

1349 Inspired by the Behavior Score concept, we have devised a reward shaping strategy for the Thinker in the reinforcement learning to circumvent illegal actions and speech that may arise during unfettered

exploration within the AI Werewolf game. The specifics of this mechanism are outlined in Table 10.
 It encompasses several key areas:

- Game result reward: The AI receives a reward based on the game's outcome (win or loss) and the survival duration.
- Action reward: for taking actions that are deemed appropriate and effective within the context of the game.
- Speech reward: incentivizing the AI to engage in communication beneficial to its goals, such as persuading other players or disseminating useful information.
- Action-Speech consistency reward: awarded for coherence between the AI's declared intentions in speech and its subsequent actions.
- Cognitive reward for Werewolves: Central to the training of a Werewolf AI is the ability to masquerade as a member of the "Good" faction. To enhance this capability, we provide a reward based on the change in identity prediction from the perspective of the "Good" players. The better a Werewolf AI can deceive the "Good" faction about its true identity, the larger the reward it receives.

Description	Reward
# Game reward	
the Good faction win, Werewolves get	-4
the Good faction win, Villagers and special roles get	+2
Werewolves win, Werewolves get	+4
Werewolves win, Villagers and special roles get	-2
Any player survives for a new day	+1
# Action reward	
the Goods vote for a Werewolf	+2
the Goods vote for a Good role	-2
the Witch poisons a Werewolf	+2
the Witch poisons a Good role	-4
the Hunter shoots a Werewolf	+2
the Hunter shoots a Good role	-4
# Speak reward	
the Seer claims his identity	+2
the Witch claims his identity	+1
the Goods correctly identify a Werewolf in the speech	+2
the Goods wrongly identify a Werewolf in the speech	-2
the Goods correctly identify a Good role in the speech	+1
the Goods wrongly identify a Good role in the speech	-1
Any player who claims that he is a Good role	+0.5
# Action-Speech correlated reward	
the Seer correctly share his inspection last night	+2
the Witch correctly share the usage of antidote or poison	+1
any player who claims the voting intention and then vote the same player	+1
# Cognition reward	
the change δ of summation of a Werewolf's identity probabilities in the Good	ls' perspective:
as the Seer	$4\bar{\delta}$
as the Witch	2δ
as the Hunter or Villagers	1δ

Table 10: Reward shaping in the RL training of the Thinker.

1404 F.5 DETAILS OF OVERALL TRAINING PROCESS

1406We provide pseudo-code in Algorithm 1; the Thinker and LLMs are trained separately in our
framework. This design choice was intentional and serves as one of the strengths of our framework.1407The separation facilitates training efficiency, as LLMs, which we employ as both Listener and
Presenter, inherently generate samples slower than the Thinker module does. Therefore, to optimize
our training process, we either employ offline RL or decouple the training between the Thinker and
LLMs. The inference workflow is as follows: Listener (LLM) -> language feature F -> Thinker (RL)
-> speech instruction I -> Presenter (LLM)

During the Thinker's training, the generated speech instructions I are treated as the new input 1413 1414 language features F for subsequent steps, allowing seamless integration of the RL training into the overall process. Our hybrid training framework incorporates both BC and PPO. During training, each 1415 game session is assigned a probability to be either a BC or an RL game. In a BC session, actions 1416 a and speaking instructions I are taken directly from human replays, bypassing Thinker inference. 1417 Conversely, in an RL session, the Thinker actively generates actions and speaking instructions. 1418 Samples from the game session are tagged as either BC or RL. For the Learner, BC samples utilize 1419 the BC loss mentioned in Equation2, whereas RL samples employ the PPO loss as described in 1420 Equation3.

1421 1422 1423

F.6 TRAINING HYPER-PARAMETERS

1424 The training hyper-parameters for the Thinker are provided in Table 11.

1425 Regarding the hyperparameters in Equation 4, the Behavioral Cloning coefficient α determines the 1426 extent to which the RL policy refers to human strategies as opposed to greedily selecting the RL 1427 strategy. We observed that as α decays to 0, We rewolves completely abandon the strategy of claiming 1428 to be the Seer due to the high difficulty for Werewolves to convincingly pretend to be the Seer and 1429 the relative challenge it poses for RL optimization. A more favorable choice is to masquerade as a 1430 villager. Therefore, we maintain a small $\alpha = 0.01$ during the later stages of training, as a constraint for human strategic preferences. Regarding the coefficient β for the identity model, we tested values 1431 in 1.0, 0.1, 0.01 and found they had minimal impact on RL, given its nature as an auxiliary learning 1432 task. The fine-tuning hyper-parameters for the Listener and Presenter are provided in Table 12. 1433

1434

1435 F.7 LLM PROMPTING FOR THE LISTENER AND PRESENTER

The information extraction prompt for the Listener module contains the following parts:

- Description of the background of the Werewolf game, as shown in Table 13, which provides the game configuration, game rules, terminology, and descriptions of roles' identities and skills.
- Task requirements, as shown in Table 14. The prompt describes the structured information in JSON format that we expect LLMs to produce, and we describe the appropriate values for each position of the structured command and limit the output within a reasonable range.
- Few-Shot examples, as in Table 16, which provides examples of correctly extracted information from the speeches of different identities and skills, to improve the accuracy of the task as well as to align it with the type of output we expect.
- Current information: Finally, we input the current speech of the player, the game state, e.g., the speaker's *Player id*, role, the current speech types, as in Table 17, to prompt LLMs for deductive reasoning.
- The speech generation prompt for the Presenter module comprises the following parts, as shown in Table 18:
- 1451
- Description of the background of the Werewolf game, which is the same as in the Listener module.
- (Optional) speech instruction. The prompt is a structured output from the Thinker module, and its meaning aligns with that of the Listener module, with a 1-shot example.
- Task requirements, which are similar to those in the Listener module except for the speech generation task.
- Current information, which is similar to that in the Listener module except that we prompt for all historical speeches.

         output the extraction results in JSON format in sequence. The format
1681
         should be:
1682
          {
              "identities": {"<identity>": [player, player, ...]}
1683
              "actions": {"<action>": [subject player -> object player,
1684
                          subject player -> object player]}
1685
         }
1686
         Example:
1687
          ł
1688
              "identities": {"werewolf":[3,5]}, {"<action>": [subject player
-> object player, subject player -> object player]}, }
1689
1690
              "actions": {"check": [1->6, 2->3]}
1691
         - This indicates Players 3 and 5 are Werewolves, Player 1 checks Player
1692
         6, and Player 2 checks Player 3.
1693
         - Player numbers can only be: 1, 2, 3, 4, 5, 6, 7, 8, 9.
1694
         - When players express their intentions, please correspond to the
1695
         identity of the player, for example, if Player 5 speaks, then consider
1696
         from the perspective of Player 5.
         - The subject number should be inferred from the context, such as
1697
         'I', 'you', 'he', 'she', etc. If unknown, use 'unknown', for example:
1698
         "check":[unknown->6].
1699
1700
         Possible JSON KEYs are:
1701
1702
         Identities:
         - Roles: Seer, Witch, Hunter, Villager, Werewolf, "Good" faction,
1703
         Werewolf faction, gold water, silver water, the Werewolves' target,
1704
         etc.
1705
         - Guess: suspicious, credible, uncertain, tolerant, etc.
1706
         - Speech: good (up), bad (down), listen well, listen to kill, etc.
         - Faction: allied, support, werewolf candidate, etc.
1707
         - Online status: disconnected, offline, not online, voice, etc.
1708
1709
         Actions:
1710
            - Skills:
1711
              - Seer:
                      check, inspect.
              - Witch: poison, save.
1712
              - Hunter: shoot, take away, crash, kill.
1713
              - Werewolf: self-destruct, explode.
1714
            - And skills that will be used in the future:
1715
              - Vote: vote out, choose a target, etc.
1716
         - Quotes from other Players' statements do not need to be summarized.
1717
         - Note the distinction between quantifiers and player numbers: must be,
1718
         that there are three Werewolves.
1719
         - Note negative statements: not, impossible, implausible, not quite,
1720
         etc.
1721
         - Note the abbreviation of number + information, e.g., "three golds,
1722
         nine slashes, one, six, eight, three wolves" results in: "identities":
          "gold water":[3], "slash":[9], "werewolf":[1,6,8]
1723
1724
1725
1726
```

```
1782
1783
1784
1785
              "identities":{"witch":[7],"gold water":[2],"werewolf":[9,5],
1786
                            "suspicious":[4]},
1787
              "actions":{"suggest to poison":[7->3],
1788
                         "believe to be a silver water": [7->1] }
1789
1790
         Player 8 spoke: "Player 5 appears highly suspicious. He could either
1791
         be a werewolf or might be deceiving his teammates. His failure to set
1792
         wolf traps, dishonesty about the wheat sequence, and excessive talking
1793
         during the first microphone turn is concerning. Players 6 and 7 might
         be superficial wolves. Player 7, however, seems to have a sensible
1794
         perspective and could be part of the good camp. I recommend voting
1795
         against Player 5."
1796
         {
1797

              "actions":{"suggest to vote":[8->5]}
1799
         }
1800
         Player 2 spoke: "Regarding the game, my suspicion falls on Players 1,
1801
         5, 7, and 3 as potential wolves. The accusation by Player 3, however,
1802
         is incorrect. I find Player 3's judgment flawed. It's frustrating.
1803
         Similarly, I suspect that Players 1, 5, 7, and 3 are wolves according
         to Player 5's perspective. Let's test this theory. I propose we
1804
         eliminate Player 5 today, and then I, as a Witch, will poison Player
1805
         7 tomorrow night. Observe the game's progression tomorrow, and you
1806
         will see that both Player 5 and I, as Witches, agree on Player 2, and
1807
         our views align with Player 3's decision. Therefore, I request that we
1808
         focus on Player 5 first."
1809
         {
              "identities":{"werewolves' target":[3],"werewolf":[1,5,7],

017	3(Villager), Player 4(Werewolf), Player 5(Villager), Player 6(Hunter),
018	Player 7(Villager), Player 8(Werewolf), Player 9(Werewolf).
)19	
)20	day 1, discussion:
021	- (random, Player 9 starts to speak)
022	- day 1 Player 9 (Werewolf) said: "Good man card, ah, the first
023	position to speak is not my specialty, you say the system and gave me
024	this right, so that I can openly paddling, hey, I especially want to
025	exercise, I will say Player 2, just more than a sentence do not say it,
026	OK? On the first day to find the next day we in that what in the look
027	at the side of the station to update the speech, okay? Player 9 is a
028	white ah, Player 9 Player 8 license plate"
029	- day I Player I (Seer) said: "Ine Player / is gold water, with a sense
030	of nearing, to fead the good guys to victory. My fast words are to
031	- day 1 Player 2 (Witch) said: "Player 7 has an average sense of
)32	bearing and cannot take sides. Player 1 listens to the situation and
133	listens to the speech - Player 7 only listens to Player 8 or Player 9
134	do the other cards enter the perspective? Player 5 is a silver water
125	cutter. I saved him. don't hold a grudge. Before Player 6. Player7
000	and Player 8 Werewolves should not be less, can go to the highest
130	identity."
137	- day 1 Player 3 (Villager) said: "I think Player 4 need be
138	intimidated, Player 7 has no sincerity, Player 9's speech is error
)39	tolerant, Player 2 keeps taking the Witch card, and he's good."
040	- day 1 Player 4 (Werewolf) said: "I'll give gold water on Player 2,
041	and Player 9 is labeled as a werewolf. Player 7 is a predecessor of
042	the Player 5 and Player 2 Werewolves. Player 3 will not be a werewolf.
043	Witch card Player 2 doesn't report silver water, which is kind of
044	cool. I'll go ahead and vote for Player 1, with a high probability
045	that Player 9 is a werewolf."
046	- day 1 Player 5 (Villager) said: "Player 4 poison Player 1, no need
047	for a Seer. Player 5 has a sense of hearing, Player 7 just doesn't
)48	fight because he respects his predecessor. Player 2 is not a one-burst,
)49	Player 9 must be saved. Convinced by virtue, vote Player 4 poison
050	Player 1 or Player 2 are marked."

2052	
0050	- day 1 Player 6 (Hunter) said. "Very well great Player 4 feel the
2053	bas had a data and to table short when the much planet a feet the
2054	back side does not need to talk about what too much, Player 2 Seer do
2055	not want it, right? If it's a werewolf, I'm sure I'd want neither."
2000	- day 1 Player 7 (Villager) said: "Deacon Player 3 is a white, Player
2056	6 is a top werewolf, Player 4, Player 6, Player 8 three Werewolves,
2057	Player 1, Player 6, Player 9 are numbered cards, Player 4 is a werewolf,
2058	Player 7 suggests betting on Player 6, and the ticket dies poison
2050	Player 1."
2039	- day 1 Player 8 (Werewolf) said: "Player 8 guestions Player 1's board
2060	and thinks he has intentions. Player 1's statement mentions checking
2061	Player 7, but it doesn't sound good. Player 4's statement is off and
2062	suggests washing the oil and playing PK table water tomorrow."
2062	
2003	day 1 voting
2064	- voting information. 1 voted for 1 2 voted for 1 3 voted for 1
2065	player 4 abstained 5 yeted for 4 6 yeted for 4 7 yeted for 4 8
2066	unted for A D unted for A
20067	voted for 4, 5 voted for 4
2007	- voting result. Flayer 4
2068	- remaining prayers: Frayer i (werework), Frayer 2 (witch), Frayer
2069	S(villager), Player S(villager), Player 6(Hunter), Player /(villager),
2070	Player 8(Werewoll), Player 9(Werewoll).
2071	
2071	day 1, last words:
2072	Player 4 (Werewolf) Last Words: "We should vote Player 5 out and
2073	poison one werewolf, I don't care if I vote them all out. Player 1
2074	poisoned Player 2, Player 2 witch tags down to find the Hunter. The
2075	Werewolves may kill Player 2 at night, the gun card should hide. Witch
2075	card not down tomorrow, you lead the team down, gun card hidden knife
2076	hook."
2077	
2078	day 2, night:
2079	- Werewolves: Player 4, Player 8, and Player 9 choose to kill Player 2.
2013	- Seer: Player 1 investigates Player 3, who is in the good camp.
2080	- Witch: Player 2 poisoned Player 1.
2081	
2082	day 2, announcement:
2083	- players who died last night: Player 1, Player 2
0004	- remaining players: Player 3(Villager), Player 5(Villager), Player
2004	6(Hunter), Player 7(Villager), Player 8(Werewolf), Player 9(Werewolf).
2085	
2086	dav 2. discussion:
2087	- start from the right of the dead player Player 3 starts to speak)
2088	day 2 Diawar 2 (William) and Higher 4 is a two way and Diawar
2000	- day 2 Player 5 (Villager) said: "Player 4 is a true pre-card, Player
2089	5 offers to vote Player 4 poison Player 1, 5, 6, 7 and 8, there is
2090	no opposition, Player7 also has a familiar moderation to him, Player
2091	4'attitude is there, it is not difficult to find a prophet. Player 6
2002	played Player 4, 6 and 8 in the werewolf pit, Player 6 and Player 7
2002	played awkwardly in the werewolf pit. I think Player 4 is the true
2093	Seer, and Player 1 is a werewolf card that goes to silver water. Vote
2094	Player 4 today, and Player 7 says work Player 4 and Player 8 whore is
2095	term Diever 4 reliere?"
2096	team Player 4 rolling?"
2007	- day 2 Player 5 (Villagers) said: "Right ah, you can hear out the
2031	Player 4 times the Seer, and other people can not hear out ah, on this
2098	chat he wrote to write he went out what is the problem ah? Eight some
2099	words should not be put on this field to say the end, you can go to say
2100	well, seven or eight shun down well, hev, over."
2101	- day 2 Player 6 (Hunter) said. "The Seer points the next seven
2101	is finished. Soven deepn't know what the card is and is completely
2102	unintalligible. Tight four prices of a line of
2103	unincerrigidie. Licket four poison one poison six dry six. Card seven
2104	must be a werewolf card."
2105	- day 2 Player 7 (Villager) said: "Seven is a polearm sign, four is
210J	probably a wolf pre, and six is probably a werewolf. Ticket seven, but
	I would go for ticket six. There is a white card and a werewolf card
	in eight or nine."

06	
07	day 2 Diayon (Manayalf) said. "Diayon 0 suggests masking silver
08	water and hammering Seven for a deep push on Werewolf. Player 6 and
09	Player 9 are two Werewolves' targets, and Player 6 is a werewolf.
10	Player 1 and Player 7 are two Werewolves, Player 7 could be the
11	werewolf. Player 9 spoke first, two white cards in Player 7 and Player
12	8 in the back seat, and all dumped gold in the front seat. Player
13	6 is the most bandit to speak, and is killed by listening. It is
14	- day 2 Player 9 (Werewolf) said: "Player 7 and Player 8 are a double
5	to play Player 6. Player 5 has returned to the ticket, and the Player
;	7 and Player 8 goes down to a point Player 7. Player 6 is a white card,
	Player 7 and Player 8 are sold."
	den O mettinge
	day 2, voting:
	votes for 6. 8 votes for 6. 9 votes for 7
	- voting result: Player 7
	- remaining players: Player 3(Villager), Player 5(Villager), Player
	6(Hunter), Player 8(Werewolf), Player 9(Werewolf).
	day 2, last words:
	Layer / (Villager) Last words: "Vote out or poison Player 4, Player
	Player 6? Player 3 may be a werewolf. Player 2 is a werewolf. leaving
	a three-in-two pattern inside the Player 8 and Player 9, and placing
	Player 3. Player 9 could be a werewolf."
	day 3, night:
	- Werewolves: Player 8, and Player 9 choose to kill Player 5.
	- Witch: the Witch is out.
	day 3, announcement:
	- players who died last night: Player 5
	- remaining players: Player 3(Villager), Player 6(Hunter), Player
	«(werewolt), Player 9(Werewolt).
	day 3. discussion:
	- start from the left of the dead player, Player 3 starts to speak)
	- day 3 Player 3 (Villager) said: "I do not know whether the double
	wolf has control of the field ah, we are empty, randomly on the three
	ends of the inside point it ah, there is no empty field on the point
	of eight, because I suddenly thought of this nine last speech is too
	brief."
	- day 5 riayer 9 (Werewoll) Sald: - policy intent.
	{

	"actions": {"suggest to vote": [[9,6]]}
	}
	- [GPT-3.5-LtM]: "On the first day, I quietly observed everyone's
	speeches, and on the second day, the debates heated up. It seems it's
	time to show my teeth. First, it must be acknowledged that Player
	5 is a villager; our fellow Werewolves have already eliminated him.
	Judging from the voting results, Player 4 is a suspicious werewolf, and
	we should keep an eye on him. Additionally, there was something off
	about Player 3's speech; he might be a werewolf too. Let's pay close
	attention to his movements and not give him a chance to escape. Now, I
	hope everyone can focus and take down the Werewolves one by one! "

2211 2212 2213

2163 2164 2165 2166 2167 - [GPT-3.5-T]: "I am Player 9, and I sincerely tell everyone that I am a villager. Based on the statements and votes of the past two days, 2168 I believe Player 6 is a werewolf, while Player 8 and I are villagers. 2169 We can cast our votes for Player 6, because his actions and words 2170 have made me feel that he is a werewolf. Let's stay vigilant and work 2171 together to find the real werewolf to ensure the peace of our village. 2172 Thank you all for listening." 2173 - [GPT-4-LtM]: "I am Player 9. Last night, we lost Player 5, which 2174 is really unfortunate. The situation is currently complex, but 2175 I believe that Player 3 is likely a werewolf. His speeches seem 2176 insincere, and he seems to hold back when analyzing the game situation. 2177 Additionally, based on the analysis of yesterday's last words, I think Player 8 is also very suspicious. He might be promoting actions that 2178 are advantageous to the Werewolves. Therefore, I suggest that today 2179 we consider voting for either Player 3 or Player 8. I have a strong 2180 intuition that one of them is a werewolf." 2181 2182 - [GPT-4-T]: "As Player 9, I'm just an ordinary villager. The situation is becoming clearer by the moment. From my perspective, 2183 Player 8 is definitely a werewolf--it's a done deal. This also 2184 explains why I strongly suggest that we vote for Player 6 today. 2185 Stating one's position clearly is important. In my view, Player 6's 2186 speeches and actions have raised many suspicions, which is the main reason I find him untrustworthy. Therefore, I will cast my vote for 2187 Player 6 and hope for your support to ensure that we can identify the 2188 real Werewolves. 2189 2190 - [WereLLM-T]: "I am Player 9. I think Player 8 might be a werewolf 2191 because his statements aren't very good. He tries to distract by targeting Player 6, and although Player 7's statements are okay, they 2192 don't provide useful information. I also suspect that Player 6 might 2193 be a werewolf, so I will vote for him. 2194 2195 - day 3 Player 8 (Werewolf) said: "Can't kill Player 8 anymore, Player 2196 8 is a werewolf come gun hang yourself." 2197 - day 3 Player 6 (Hunter) said: "Player 6 is a Werewolf, step on." 2198 day 3, voting: 2199 - voting information: 3 abstained, 6 voted for 6, 8 abstained, 9 voted 2200 for 6. 2201 - voting result: Player 6 2202 game result: 2203 the Werewolves win the game. (final surviving player: Player 3 2204 (Villager), Player 8 (Werewolf), Player 9 (Werewolf)) 2205 2206 2207 Table 19: Werewolf game log example. 2208 2209 2210
