PATIENT- Ψ : Using Large Language Models to Simulate Patients for Training Mental Health Professionals

Anonymous ACL submission

Abstract

Mental illness remains one of the most critical public health issues. Despite its importance, many mental health professionals highlight a disconnect between their training and actual real-world patient practice. To help bridge this gap, we propose PATIENT- Ψ , a novel patient simulation framework for cognitive behavior therapy (CBT) training. To build PATIENT- Ψ , we construct diverse patient cognitive models based on CBT principles and use large language models (LLMs) programmed with these cognitive models to act as a simulated therapy patient. We propose an interactive training scheme, PATIENT- Ψ -TRAINER, for mental health trainees to practice a key skill in CBT - formulating the cognitive model of the patient - through role-playing a therapy session with PATIENT- Ψ . To evaluate PATIENT- Ψ , we conducted a comprehensive user study of 13 mental health trainees and 20 experts. The results demonstrate that practice using PATIENT- Ψ -TRAINER enhances the perceived skill acquisition and confidence of the trainees beyond existing forms of training such as textbooks, videos, and role-play with non-patients. Based on the experts' perceptions, PATIENT- Ψ is perceived to be closer to real patient interactions than GPT-4, and PATIENT- Ψ -TRAINER holds strong promise to improve trainee competencies. We will release all our code and data upon acceptance of this paper.

1 Introduction

One in eight people globally are living with mental health conditions (World Health Organization, 2023)¹. However, there is a significant gap between the available mental health support and patient needs, with over half (54.7%) of adults with a mental illness receiving no treatment in the US². Train-

world-mental-health-day/2023

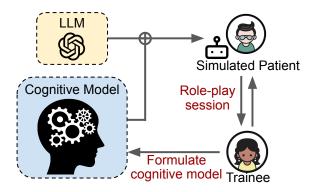

Figure 1: Illustration of our patient simulation idea.

ing mental health professionals requires extensive effort, yet many professionals highlight a disconnect between their training and the complexities of real patient interactions. To understand these training challenges, we conducted a formative study involving semi-structured interviews with twelve mental health experts and trainees. This diverse group comprised of clinical psychologists, licensed social workers, and current master's students in social work. The experts provided insights into the difficulties faced when transitioning from formal CBT training to real-world practice (details in Appendix A). All experts noted that their training did not adequately prepare them for the unpredictable and multifaceted nature of real patient interactions. Despite wanting more interactive experiences, they found role-playing exercises with peers, a common training method, to be unrealistic, as these exercises often do not reflect actual therapy sessions.

There has been growing interest in developing LLM-based methods for psychology (Demszky et al., 2023; Chen et al., 2023b). In (Bubeck et al., 2023; Kosinski, 2023), ChatGPT and GPT-4 are able to solve some basic theory of mind tasks that generally require the ability to understand and attribute mental states to oneself and others. Inspired by such promise, we propose to use LLMs to simulate patients to train mental health professionals,

real patient interactions. However, two major challenges must be addressed to realize this idea: Fidelity. How can we build simulated patients that

closely resemble the communicative behaviors of real patients with mental health disorders?

with the goal of bridging the gap between their

existing training methods and the complexities of

Effectiveness. How can we design an effective training scheme that allows trainees to benefit from interacting with these simulated patients?

In this work, we claim that integrating a patient's cognitive model with an LLM can achieve high fidelity in simulating real patients with mental health disorders corresponding to that cognitive model. We implement this idea using the cognitive modeling framework in CBT (Beck, 2020), a popular paradigm in psychotherapy. We propose PATIENT- Ψ , a novel simulated patient agent that integrates cognitive modeling with LLMs. We collaborate with clinical psychologists to curate a dataset, PATIENT- Ψ -CM, which comprises 106 high-quality and diverse patient cognitive models. These cognitive models cover unhealthy cognitive structures embedded in multiple contexts, such as family issues, relationship problems, workplace challenges, and more. We then use these cognitive models to program an LLM to act as the PATIENT- Ψ agent. To better resemble the complex dynamics of real patient communications within a therapy session, we also integrate six conversational styles into PATIENT- Ψ . These conversational styles were identified from our formative study with mental health domain experts.

In CBT, formulating a patient's cognitive model is a crucial skill that therapists need to learn (Beck, 2020). Our design of PATIENT- Ψ naturally incorporates a feedback mechanism for trainees to practice this skill without extensive need for supervisor intervention, which is a desired benefit of AI-based training. We propose PATIENT- Ψ -TRAINER, an interactive training framework for mental health trainees to practice CBT cognitive model formulation using PATIENT- Ψ . Specifically, trainees converse with the simulated patient, PATIENT- Ψ , to formulate its cognitive model. Afterward, the system displays the original cognitive model that was used to program the simulated patient as a reference, allowing trainees to compare their results as feedback. Within this training framework, the effectiveness of the feedback theoretically depends on how accurately PATIENT- Ψ simulates a real patient with the corresponding cognitive model. Figure 1

illustrates the overall idea of our framework.

To evaluate the fidelity of PATIENT- Ψ and the effectiveness of PATIENT- Ψ -TRAINER, we conducted a thorough user study with 20 mental health experts and 13 trainees. Evaluation results from the experts indicate that: (1) PATIENT- Ψ closely resembles real patients in terms of maladaptive cognitions, conversational styles, and emotional states; outperforming GPT-4. (2) Practicing with PATIENT- Ψ -TRAINER is perceived to be highly beneficial for improving CBT formulation skills and better-preparing trainees for interactions with real patients. Experts also highlighted several advantages of PATIENT- Ψ -TRAINER, including customized options to choose conversation styles and the diverse patient cognitive models. Evaluation results from the trainees indicate that practicing with PATIENT- Ψ -TRAINER is perceived to improve skill and confidence, compared to current training methods. Overall, experts and trainees prefer using PATIENT- Ψ -TRAINER over a strong GPT-4 baseline. We also demonstrate that automatic evaluations with LLMs fail to assess the simulated patient fidelity, indicating the challenge of our task. Our contributions are summarized as follows:

- We propose PATIENT- Ψ , a novel simulated therapy patient, built using cognitive models grounded in psychology principles and LLMs.
- We propose PATIENT- Ψ -TRAINER, an interactive training framework for trainees to practice CBT formulation skills on PATIENT- Ψ .
- We create and release a dataset, PATIENT- Ψ -CM, with high-quality CBT-based cognitive models curated by clinical psychologists.
- Our user study with both mental health trainees and experts demonstrates that PATIENT- Ψ exhibits high fidelity to real patients, and practicing with PATIENT- Ψ -TRAINER significantly improves perceived skills and confidence in CBT formulation.

2 Methodology

In this section, we first describe the construction of PATIENT- Ψ in §2.1. We detail the integration of cognitive models with LLMs and the incorporation of conversational styles to accurately mimic real patient interactions. Next, we explain the training framework, PATIENT- Ψ -TRAINER, in §2.2, which utilizes PATIENT- Ψ to create an interactive learning environment for practicing CBT formulation skills. Figure 2 provides an overview of our method.

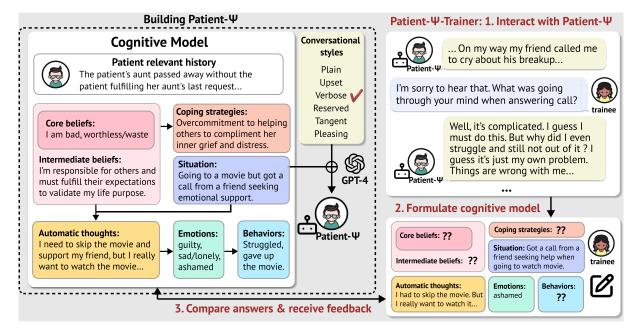

Figure 2: The overall framework of PATIENT- Ψ and PATIENT- Ψ -TRAINER. We integrate the expert-created cognitive model with GPT-4 to build PATIENT- Ψ . In PATIENT- Ψ -TRAINER, the trainee role-plays a therapy session with PATIENT- Ψ to formulate its cognitive model. The trainee can compare their formulation with the cognitive model used to build PATIENT- Ψ to get feedback.

Using Cognitive Models to Simulate Patients. *Cognitive models* in mental health provide a structured framework for understanding how an individual's thoughts and beliefs are interconnected and influence emotions and behaviors. In established therapy paradigms like CBT (Beck, 2020), formulating a patient's cognitive model is central for a therapist to understand and address the maladaptive cognitions maintaining distress and symptoms (Hollon and Beck, 2013; Hofmann et al., 2012).

The Cognitive Conceptualization Diagram (CCD) (Beck, 2020) is a commonly used representation of a patient's cognitive model in CBT. The left side of Figure 2 depicts an example CCD-based cognitive model, illustrating eight key components. (1) *Relevant history* contains significant past events that contribute to an individual's mental state. (2)Core Beliefs are deeply ingrained perceptions about oneself, others, and the world. (3) Intermediate beliefs are the underlying rules, attitudes, and assumptions derived from core beliefs and shape an individual's thought patterns. (4) Coping strategies are techniques used to manage negative emotions. An external event or context ((5) *a situation*) may trigger quick, evaluative thoughts without deliberation (6) automatic thoughts) stemming from the beliefs, leading to responses in terms of (7) emotions and (8) behaviors. A CCD-based cognitive model links the components together, creating a

framework for identifying and understanding patients' underlying cognitive processes. For all the components, we adopt the definitions and formulations put forth by (Beck, 2020). These include: three major core beliefs (②)—helpless, unlovable, and worthless—each with several fine-grained core beliefs, for a total of 19 core belief categories; 9 emotion (⑦) categories; the rest of the components are formulated as free-text entries. See Table 2 and Appendix B.1 for the categories. In this work, we integrate CCD-based cognitive models into an LLM to simulate patients whose communication reflects the underlying cognitive processes.

The PATIENT- Ψ **-CM Cognitive Model Dataset.** To the best of our knowledge, no existing work offers a dataset of realistic cognitive models due to two challenges: 1) the data privacy constraints involved in acquiring real patient cognitive models and 2) the high-level expertise required to perform manual creations. In this work, we propose the first dataset of CCD-based cognitive models grounded in CBT principles, PATIENT- Ψ -CM, created by clinical psychologists. We first prompt GPT-4 Turbo (OpenAI, 2023) to create summaries from therapy session transcripts. These transcripts were obtained from the Alexander Street database³ under the subject "Counseling and Therapy" and the keyword "Cognitive Behavioral Therapy". Two

clinical psychologists then manually create cognitive models by drawing inspiration from the transcript summaries, incorporating their professional expertise, and applying their creativity (within clinical constraints). This process involves developing new cases inspired by the summaries and composing the corresponding cognitive models. We emphasize *diversity* and *realism* to the psychologists when creating the models. We end up with a dataset containing 106 cognitive models (an example is shown in Figure 2, left). Each cognitive model is associated with one activating situation. See Appendix B.2 for details of dataset creation and more example cognitive models from PATIENT- Ψ -CM.

Conversational Styles Integration. In the for-241 mative study (Appendix A), domain experts em-242 phasized that real patients exhibit different con-243 versational styles during therapy. Based on these 244 discussions, we identify six styles for PATIENT- Ψ , 245 detailed in Table 1. To create a natural curriculum, the styles are two levels of difficulty. The 247 easiest style, plain, features direct and straightforward communication. The more difficult styles require trainees to exert more effort to elicit relevant information. To incorporate these styles with PATIENT- Ψ , two clinical psychologists annotate each cognitive model with a list of valid conversa-253

tional styles and develop instructions for PATIENT- Ψ to simulate a patient for each style. Detailed descriptions and examples of the conversational styles are provided in Appendix B.3.

Patient Agent Simulation. We prompt GPT-4 to build PATIENT- Ψ which consists of a patient's cognitive model, the conversational style prompt, and a list of instruction prompts. Appendix B.4 contains the full prompts. The model is continually prompted to engage in a CBT-based therapy session, role-playing a patient with the corresponding cognitive model and conversational styles.

2.2 PATIENT-\Psi-TRAINER

With the development of PATIENT- Ψ , we introduce PATIENT- Ψ -TRAINER, an interactive training framework designed for mental health professionals to practice cognitive model formulation for CBT. PATIENT- Ψ -TRAINER offers a structured, three-step training process: 1) engaging with PATIENT- Ψ in a simulated CBT session, 2) formulating PATIENT- Ψ 's cognitive model through interaction, and 3) reviewing the original cognitive model used to create PATIENT- Ψ for feedback. The right-hand side of Figure 2 illustrates this process.

Training Process. Trainees begin by choosing one of the six conversational styles from PATIENT- Ψ -TRAINER's web application interface (screenshots in Appendix F). Then, a patient is generated using the chosen style and a randomly-selected cognitive model from PATIENT- Ψ -CM compatible with that style. The interface displays the patient's relevant history in preparation for the session. During this session, the trainee engages with PATIENT- Ψ , applying their therapeutic skills with the goal of formulating the CCD-based cognitive model used to program PATIENT- Ψ . This involves eliciting and summarizing all cognitive elements underlying the conversation with PATIENT- Ψ .

Real-Time Feedback. Upon concluding the interactive session, PATIENT- Ψ -TRAINER allows the trainee to compare their formulated cognitive model with the original cognitive model used to program PATIENT- Ψ . This side-by-side comparison highlights discrepancies, providing detailed feedback. Trainees can continue to chat with PATIENT- Ψ to refine their formulations. This natural feedback loop, stemming from our design of using the cognitive model to program the patient, offers the advantage of minimal human supervision efforts, enabling trainees to practice independently.

We now present the experimental setup for evaluating PATIENT- Ψ and PATIENT- Ψ -TRAINER. We aim to answer the following research questions:

- RQ 1 **Fidelity:** Does PATIENT- Ψ improve the fidelity of patient simulations compared to baselines?
- RQ 2 Accuracy: How closely does PATIENT- Ψ imitate the underlying cognitive model?
- RQ 3 Effectiveness: Do experts and trainees perceive PATIENT- Ψ -TRAINER as an effective tool for CBT training?
- RQ 4 **AutoEval:** Can we leverage existing methods, such as LLMs, to automatically evaluate the patient simulations?

In §4, we answer the first three RQs through our user study with both trainees and experts. Then, in §5, we show that current automatic evaluations cannot capture the nuances necessary for conducting highly technical, domain-specific assessments. This finding not only shows the importance of user study evaluations but also motivates future work on performant automatic evaluators.

Evaluation Dimensions. We design a set of finegrained dimensions to assess each RQ, using insights from the formative study and existing literature (Beck, 2020; Bouter et al., 2012; Issenberg et al., 2005; Silverman et al., 2013; Ekman, 1992). To ensure that the simulated patients' responses reflect those of real patients, we measure the fidelity of the emotional states, conversational styles, and maladaptive cognitions of PATIENT- Ψ to real patients. To assess the **accuracy** of PATIENT- Ψ in emulating the underlying expert-validated cognitive model, we evaluate each component's accuracy. To assess the effectiveness of PATIENT- Ψ -TRAINER, we measure the perceived improvements of CBT formulation skills: *identifying maladaptive* thinking patterns and identifying beliefs. We also measure the perceived confidence improvement of the trainees. Finally, we assess usability to ensure the tool's ease of use for users. Due to space constraints, the usability results are in Appendix D.4.

For pairwise comparisons, the options are: "A is much better than B," "A is somewhat better than B," "about the same," "B is somewhat better than A," and "B is much better than A." We map the results to a scale from -2 to 2, where ± 2 indicates a strong preference. Individual measures use a 5-point Likert scale from 1 to 5, where 5 means "strongly agree" or "extremely accurate," and 1 means "strongly disagree" or "not accurate at all." Specific values for each dimension are in §4.

Baselines. We leverage vanilla GPT-4 with a general description of patients with depression or anxiety as the input, rather than the cognitive models (see Appendix C). Thus, we cannot show the reference cognitive model as feedback and do not include the conversational styles. We also compare with existing training techniques, which includes peer role-plays or textbook examples.

User Study Details. Assessing simulated therapeutic dialogue is a cognitively difficult process that requires professional training and experience, making typical crowdsourcing data collection approaches difficult. To ensure high-quality evaluations from those with significant real patient experience (experts) and from the population who would use PATIENT- Ψ -TRAINER in practice (trainees), we recruit 20 current mental health practitioners and 13 social work students, respectively.⁴ §7 details the IRB approval and recruitment. Each participant practices with PATIENT- Ψ -TRAINER and the baseline in a randomized order, completing two simulated patient sessions for each. To ensure comprehensive evaluation across diverse cognitive models, we assign each participant simulated patients with distinct underlying cognitive models, covering a total of 66 cognitive models from PATIENT- Ψ -CM. For expert evaluations, we distribute two specific conversational styles to each participant to achieve an overall balanced distributions of all styles. Trainees can select two styles based on their expertise level and confidence. More protocol details are in Appendix C.

4 User Study Results

4.1 RQ 1: Fidelity to Real Patients

To assess the fidelity of PATIENT- Ψ to real patients, experts compare existing training techniques, the GPT-4 baseline, and PATIENT- Ψ (Table 3). We ask experts for their overall impressions of these training methods, resulting in 20 data points for each comparison in this subsection. Paired t-tests show that PATIENT- Ψ significantly outperforms the other methods ($p < 10^{-4}$), indicating that PATIENT- Ψ provides the most realistic patients, addressing RQ

⁴We recruited participants through the professional networks of our co-authors in mental health (clinical psychologists and professors in clinical psychology and social work), as well as snowball sampling.

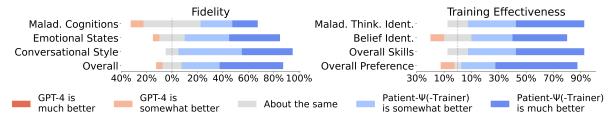

Figure 3: Fidelity of PATIENT- Ψ and training effectiveness of PATIENT- Ψ -TRAINER compared to GPT-4 baseline along multiple dimensions. X-axis: the % of experts who voted for a specific option; y-axis: the assessment dimension. Malad. means maladaptive, Think. means thinking, and Ident. means identification. PATIENT- Ψ more closely resembles real patients (fidelity, left) and is considered more effective for trainees (training effectiveness, right).

1 positively. This is promising for PATIENT- Ψ : our formative study highlighted a gap in trainee preparation for real interactions, which PATIENT- Ψ can effectively fill.

400 401

402

403

426

427

428

429

PATIENT- Ψ exhibits higher fidelity to real pa-404 tients than the GPT-4 baseline. Each expert 405 compares the fidelity dimensions (*emotional states*, 406 conversational styles, maladaptive cognitions) of 407 PATIENT- Ψ and the GPT-4 baseline to real patients. 408 Figure 3 (left) depicts the distribution of expert 409 comparisons; summary statistics in Table 11, Ap-410 pendix D. PATIENT- Ψ is rated higher along all di-411 mensions for fidelity: it better represents the mal-412 adaptive cognitions (μ : 0.6, p < 0.05), the emo-413 tional states (μ : 1.1, $p < 10^{-4}$), and the conver-414 sational styles (μ : 1.3, $p < 10^{-4}$) of real patients. 415 Experts expressed that PATIENT- Ψ offered a more 416 realistic challenge of extracting information from 417 patients, unlike the baseline which was too forth-418 coming with responses. One expert noted that ses-419 sions with the baseline felt "almost like doing ther-420 apy with a therapist," highlighting the challenge 421 of simulating real patient behavior — even with 422 advanced LLMs likely pretrained on an extensive 423 corpus of therapy knowledge. 424

425 4.2 RQ 2: Accuracy to Cognitive Model

To be practically useful, PATIENT- Ψ must accurately reflect the reference cognitive model, as trainees rely on it for feedback on their completed formulations. Experts evaluate PATIENT- Ψ 's over-

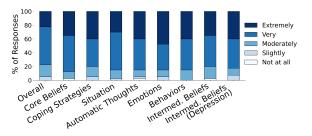

Figure 4: Experts rate 97% of the PATIENT- Ψ patients as at least moderately accurate in reflecting the reference cognitive model. Intermed. means Intermediate.

all accuracy and its accuracy for each component of the cognitive model, resulting in 40 data points per dimension. Table 12, Appendix D.2 presents the summary statistics; Figure 4 illustrates the distribution. The results are promising: overall, PATIENT- Ψ is rated on average as *very accurate*. For each of the 8 components, PATIENT- Ψ is rated on average as *very* to *extremely* accurate. Specifically, 80-88% of the simulated patients achieve *very* to *extremely accurate* ratings for each of the 8 components, answering RQ 2. Crucially, since the reference cognitive model is accurately captured by PATIENT- Ψ , trainees can rely on it to receive high-quality feedback on their responses.

4.3 RQ 3: Effectiveness for Training

Experts and trainees provide their perception of the effectiveness of PATIENT- Ψ -TRAINER and the GPT-4 baseline compared to existing training techniques. In this section, we have 20 comparison points for the experts and 13 for the trainees, as we ask them to provide their *overall* assessment of the tool, not individual patients. Paired t-tests reveal that experts and trainees perceive PATIENT- Ψ -TRAINER as significantly more effective at improving overall skills than both traditional techniques ($p < 10^{-4}$) and the GPT-4 baseline (p < 0.01) (Table 4), answering RQ 3. Compared to trainees with limited real patient experience, experts show stronger preferences for our system, further demon-

strating PATIENT- Ψ -TRAINER's effectiveness in 459 460 preparing for real patient interactions. Compared 461 to traditional methods without real patient interactions, experts favor PATIENT- Ψ -TRAINER's ease 462 of access (90%), customization options of different 463 conversational styles (90%), and interactive experi-464 ence (65%). Compared to practicing with real pa-465 tients, experts value PATIENT- Ψ -TRAINER's ease 466 of access (79%), customization options of different 467 conversational styles (88%), and safer setting for 468 training (88%). After only two sessions with our 469 tool, one trainee remarked that it "helped to make 470 things more clear with the CCD (cognitive model), 471 472 for my training/class it was somewhat meaningless and challenging to build one." 473

PATIENT- Ψ **-TRAINER is a more effective train-**474 ing tool than the GPT-4 baseline. Both groups 475 compare PATIENT- Ψ -TRAINER and the GPT-4 476 baseline along the fine-grained dimensions. Fig-477 ure 3 (right) shows the distribution of expert com-478 parisons; summary statistics for both groups in Ta-479 ble 13, Appendix D. Both groups indicate that 480 PATIENT- Ψ -TRAINER would be significantly more 481 effective at improving the key CBT skills of identi-482 fying beliefs (μ : 1.0, p < 0.01; μ : 0.9, p < 0.05, 483 respectively) and maladaptive thinking (μ : 1.4, 484 $p < 10^{-4}$; μ : 1.0, p < 0.01, respectively). 485 Furthermore, both groups overwhelmingly prefer 486 PATIENT- Ψ -TRAINER for practical use (both μ : 487 1.4, $p < 10^{-4}$), showing its high potential for real-488 world impact. 489

PATIENT- Ψ -TRAINER can improve trainees' confidence over the baseline and traditional methods. Toward our aim of improving preparation for real patient interactions, trainees compare their perceived confidence improvement when using PATIENT- Ψ -TRAINER versus traditional methods and the GPT-4 baseline. They rate PATIENT- Ψ -TRAINER as significantly more effective at boosting their confidence (Table 5).

Experts unanimously find value in PATIENT- Ψ **-TRAINER 's real-time feedback.** A core feature of PATIENT- Ψ -TRAINER is the real-time feedback provided by displaying the accurate reference cognitive model (§4.2). 100% of experts prefer that PATIENT- Ψ -TRAINER display the reference cognitive model at the end of training and unanimously agree that viewing it is beneficial for practicing CBT skills. One expert emphasized, "Without the answers, I think it's much less helpful."

Experts unanimously prefer PATIENT- Ψ -TRAINER's option to practice with different conversational styles. Another core feature of our method is the option to practice with patients exhibiting different conversational styles. 100% of experts prefer this option. One expert noted that the styles "are more reflective of actual patients" and can be linked to specific diagnoses and symptoms, making the interactions more accurate. Nearly all experts (95%) view this feature as useful for interacting with diverse real patients and improving trainee confidence for real interactions. These results suggest that offering diverse patient types is critical for effective and realistic training.

5 Automatic Evaluation Results

Given the potential of using LLMs for evaluating text generation quality (Chiang and Lee, 2023), we attempt to automatically assess **the fidelity and ac-curacy of PATIENT-** Ψ **and the baseline** using two state-of-the-art LLMs as evaluators: GPT-4 (Ope-nAI, 2023) and Llama 3 70B (AI@Meta, 2024). We evaluate over the 40 conversation histories be-tween the experts and PATIENT- Ψ in our user study.

LLM-based evaluators tend to underestimate PATIENT- Ψ 's fidelity in favor of GPT-4 baseline. Following RQ 1 (Fidelity), the LLMs are prompted to provide ratings on a 5-point Likert scale assessing the fidelity of how closely the simulated patient resembles real patients following the same dimensions used in the user study. In Figure 5, paired t-tests show that the fidelity of PATIENT- Ψ , as eval-

615

616

617

618

569

570

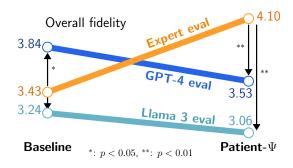

Figure 5: Mean overall fidelity of PATIENT- Ψ and baseline as evaluated by experts and LLMs. Compared to experts, both GPT-4 and Llama 3 demonstrate opposite trends.

Text-based	Acc.	Categorization	F1	F1 (expert)
Situation	0.97	Core beliefs	0.80	0.77
Coping strategies	0.93	Emotions	0.72	0.74
Intermediate beliefs	0.92	Core beliefs	0.49	0.44
Automatic thoughts	0.88	(fine-grained)	0.48	0.44
Behaviors	0.84			

Table 6: Accuracy and Macro F1 of PATIENT- Ψ evaluated by GPT-4. For text-based fields, GPT-4 is prompted to select the components among four distractor options randomly sampled from PATIENT- Ψ -CM. For categorization, GPT-4 is prompted to select all relevant categories of emotions and core beliefs.

uated by both LLMs, is consistently lower than expert evaluation, contrasting with the user study results. GPT-4 assigns the highest fidelity scores to the GPT-4 baseline. All fidelity dimensions demonstrate the same trend (see Appendix E).

557

558

564

568

GPT-4 assesses PATIENT- Ψ 's accuracy similarly to experts. To evaluate the accuracy of PATIENT- Ψ in reflecting the underlying cognitive models, we design proxy measures to prompt GPT-4 to select the closest cognitive model components reflected by the conversation. As shown in Table 6, GPT-4 achieves high accuracy in most components, except for fine-grained core beliefs, where there are 19 categories and demonstrate high variance by nature. GPT-4 achieves similar scores with the experts' inputs, suggesting the high accuracy of PATIENT- Ψ in representing the underlying cognitive models, aligning with the experts' evaluations.

The results suggest that GPT-4 excels in understanding cognitive models from patients' conversations, attributable to its extensive acquisition of CBT knowledge during pre-training. However, it falls short in assessing the realism of patients. This aligns with our findings that the GPT-4 baseline fails to create high-fidelity patient simulations. While it accurately conveys CBT knowledge, it does so in a manner resembling a therapist speaking directly and explicitly, rather than a real patient whose conversation naturally reflects their disorders. This underscores the challenges and contributions of our work, highlighting the difficulty of crafting realistic patient interactions even with the most powerful LLMs today.

6 Related Work

Our work is broadly related to the recent use of LLMs in psychology, education, and computational social science (Hsu et al., 2023; Chiu et al., 2024; Fu et al., 2023; Ji et al., 2022; Zanwar et al., 2023; Juhng et al., 2023; Ziems et al., 2024; Halder et al., 2017; Sharma et al., 2020b,a; Atapattu et al., 2022; Mishra et al., 2023; Sonkar et al., 2023; Wang et al., 2024; Zhou et al., 2024). In contrast to existing research on using LLMs for CBT, which focuses on cognitive distortion detection (Shreevastava and Foltz, 2021; Ding et al., 2022; Lybarger et al., 2022; Chen et al., 2023b) and negative thoughts reframing (Sharma et al., 2023, 2024), our work aims to provide realistic and interactive scenarios for CBT professional development by simulating diverse patient types using LLMs. As a result, our work most closely relates to research that leverages LLMs for simulation-based training, particularly communication skill learning and emotion management grounded in dialectical behavioral therapy (Lin et al., 2024), social skill training (Yang et al., 2024), and clinical diagnosis (Chen et al., 2023a). Our work is the first to ground LLMbased simulations in clinical psychology theory by leveraging CBT-based cogntive models to program LLMs, incorporate a natural curriculum and feedback mechanism in the training tool, and perform evaluation in context with mental health trainees and professionals rather than crowdworkers.

7 Conclusion

In this paper, we introduce PATIENT- Ψ , a simulated patient that integrates cognitive models with an LLM to accurately mimic the communicative behaviors of real patients. We propose PATIENT- Ψ -TRAINER, where trainees engage in role-playing therapy sessions with PATIENT- Ψ and attempt to formulate the underlying cognitive model. User studies with both mental health experts and trainees demonstrate the high fidelity of PATIENT- Ψ and the training effectiveness of PATIENT- Ψ -TRAINER, showing improvements over existing training methods and outperforming a GPT-4 baseline. Our framework has the potential to transform mental health professional training and be generalized to broader training protocols and therapy paradigms.

Limitations 619

In this work, our measures of the training effectiveness are all perceived improvements from the 622 participants after they practice with PATIENT- Ψ -TRAINER for two sessions. Measuring objective skill improvements could take the form of longitudinal randomized controlled trials (RCT). We leave 625 this for future work. While we primarily target CBT cognitive formulation training in this paper, we believe our methodology can be generalised to other training protocols and therapy paradigms.

Ethics Statement

631

641

644

653

654

IRB (Institutional Review Board) Approval. This project is approved by our Institutional Review Board (IRB) with study number [omitted]. 633 For the creation of cognitive models, any other annotation work, as well as consultations, we collaborate with clinical psychologists and professors 636 in clinical psychology and social work, who are our co-authors. For both the formative study and user study, we recruited participants through the professional networks of our co-authors, as well as snowball sampling. Experts are defined as those with a graduate degree in clinical psychology, social work, or other related majors and have worked 643 with at least 5 patients. Trainees are those still in school/training or with fewer than 5 real patient experiences. For the formative study, we recruited a total of 12 participants. We pay a \$30 Amazon gift card for each participant for a 30-minute session over Zoom. For the user study, we recruited a total of 33 participants. We pay a \$60 Amazon gift card for a 60-90-minute session over Zoom.

Informed Consent. All participants in the user study and formative study were 18 or older and provided informed consent. We did not assess any clinical outcomes. All data collected from the participants were de-identified and consented to be released for research purposes.

Crisis Resources The risk to the participants is minimal, no greater than their professional working or training environment of mental health support in the context of conducting therapy sessions with people with mental health issues. Nevertheless, we do not exclude the possibility that some AI-generated content might still be upset-664 ting to the participants. Therefore, we advise participants to use a free crisis resource available at https://www.7cups.com/ if needed, and they are 667

free to terminate the study at any time without facing any negative consequences. This risk assessment and crisis resource information have been included in our IRB approval and provided as part of the informed consent to participants.

System and Data Usages. All the data and systems developed in this work are intended solely for academic research purposes. The systems developed in this work are intended to augment existing mental health training, not to replace it. One major benefit of our system, as highlighted by experts in the user study, is that it provides trainees with a safe training environment. By working with AI patients, trainees can practice without the risk of causing actual harm due to mistakes made during simulated therapy sessions. Our system is designed for academic and educational purposes only. Real-world deployments will require further work, including measuring objective skill improvements and developing protocols for integrating the system with existing training methods, all within the framework of large-scale randomized controlled trials (RCTs).

We utilize therapy session transcripts from the Alexander Street database⁵, accessed through our institution subscription. Our usage complies with their fair use policy. GPT-4 is employed to generate summaries of these transcripts. For constructing the cognitive model dataset, two clinical psychologists manually create cognitive models based on inspirations from the transcript summaries, clinical experience, and creativity-effectively generating new cases. The resulting dataset is manually verified and does not contain any Personally Identifiable Information (PII). It is intended solely for academic research purposes and will be made available only to academic institutions with subscriptions to the Alexander Street database. The dataset will be released upon request after the publication of our paper.

A **Formative Study Details**

913

To understand the challenges faced during CBT 914 training and elicit feedback on a prototype of 915 PATIENT- Ψ -TRAINER, we first conducted a forma-916 tive study in the form of semi-structured interviews 917 with trainees and experts in mental health.⁶ This 918 study was conducted over Zoom. 919

Participant Information. We interviewed 921 twelve individuals who had diverse educational backgrounds and career experiences. Among them, five were Master's students, the rest included a 923 Ph.D. student, a post-doctoral fellow, three licensed social workers, and two psychologists. Our 925 participants also had varied levels of experience working with patients. Only one individual had 927 not yet worked with any patients, while another reported working with anywhere from 1500-3000 929 patients over their career. We refer to individuals 930 as experts if they received a graduate degree and 931 have worked with at least 5 patients; we use 932 trainees if they do not have a graduate degree and 933 have formal experience with fewer than 5 patients. This definition is consistent with our user study. 935 Thus, for our formative interviews, we have 5 trainees and 7 experts. 937

Instructions to Participants. Before each interview, the participant voluntarily signs the consent 939 form. We provide the screenshots of the consent form with all sensitive information removed in Fig-941 ures 6 and 7. After receiving the signed consent 942 form, we then proceed with the interview. When 943 the session starts, we remind participants of the recorded nature of the conversation and verbally summarize the goal of the interview. We also pro-947 vide a high-level overview of the structure of the interview. We confirm consent to audio record the 948 interview before proceeding. In our interviews, we first ask the experts questions about challenges they faced transitioning from their formal CBT training 951 952 to practice. We then present both groups with a proto type of PATIENT- Ψ -TRAINER to elicit feedback. 953

A.1 Insights

954

955

957

958

We now elaborate on the main insights that we gleaned from this formative study.

Insight 1: Experts feel that their training did not adequately prepare them for real-world prac-

Consent Form

Purpose of this Study This study aims to understand the current landscape of Cognitive Behavioral Therapy (CBT) training, including the need, constraints, and potential challenges of implementing LLM-based simulation

In this study, we will conduct semi-structured interviews to gather your insights. You will answer a series of questions about your experiences with CBT training.

terview will take approximately 30 minutes. The interview will be held over Zoom and audio-recorded for ch purposes. Participants should ensure their camera is off to avoid video recording. If you prefer not to be recorded, you may oft but of the study. Please do not share any identifiable, personal or sensitive informatior yourselves or others that you would not want shared outside the research setting.

Participant Requirements

1. Participants must be 18 years and older

2. Participants must be

(1) college students who are currently studying or have previously studied CBT or

(2) Social workers who are receiving or have previously received CBT training or

(3) Professional CBT therapists with in-depth knowledge of CBT training who have experience in interacting with real-world patier

3. Participants must have the ability to sign the consent form

4. Participants must be in the United States during the time of participation

Benefits Participants may find it interesting to share their experiences with CBT training and help the researchers to design patient simulation system. The publication of this research can benefit the research community.

Compensation & Costs You will receive a \$30 Amazon gift card for compensation. Your participation in the study is at no cost

Future Use of Information

once we have removed all identifiable information from your data, we may use the data for our future research studies, or we may distribute the data to other investigators for their research studies. We would do this without getting additional informed consent from you (or your legally authorized representative). Sharing of data with other researchers will only be done in such a manner that you will not be identified.

Figure 6: Screenshot of formative study consent form - 1

The risk to you is minimal, no greater than in ordinary life, in the context of discussions about CBT training. There are potential risks of a breach of confidentiality, and boredom or fatigue out your experiences with

Rights

Rights Your participation is voluntary. You are free to stop your participation at any point. Refusal to participate or withdrawal of your consent or discontinued participation in the study will not result in any penalty or loss of benefits or rights to which you might otherwise be entitled. The Principal Investigator may at his/her discretion remove you from the study for any of a number of reasons. In such an event, you will not suffer any penalty or loss of benefits or rights which you might otherwise be entitled.

estudy will collect your research data through your use of Google, Zoom and Otter.ai. These companies are not med by <u>use</u>. The companies will have access to the research data that you produce and any identifiable ormation that you share with them while using their product. Please note that <u>the transmit</u> does not control the rms and Conditions of the companies or how they will use or protect any information that they collect.

Data Storage and Access All study data will be securely stored at **1000**, accessible only to the re recordings will be transcribed and then deleted from third-party services. Personal identifiers will

Right to Ask Que

to Ask Questions & Contact Information have any questions about this study, you should feel free to ask them now. If you have questions late nai Information, or wish to withdraw your participation please contact the Principal Investigator by ma ail in accordance with the contact information listed on the first page of this consent. vestigator by mail, phone

If you have questions pertaining to your rights as a research participant; or to report concerns to this study, you should contact the

⁶We recruited participants through the professional networks of our co-authors in mental health (clinical psychologists and professors in clinical psychology and social work).

tice. 100% of experts noted that their training did not adequately prepare them for the complexities of real-world practice, where patients often experience co-occuring challenges, such as other mental health issues or poverty. Experts found role-playing exercises with their peers based on manuals to be unrealistic, as these exercises often do not reflect the unpredictable nature of actual sessions. One participant explained,

959

960

961

962

963

964

965

967

968

969

970

994

995

Manuals can often make it feel quite clean. But then when you're in the room with the patient, what they're actually saying can feel very messy.

This gap made it difficult for some experts to develop confidence in their skills: the examples were too perfect to apply in practice.

Insight 2: Fidelity is a crucial aspect of any 971 simulation-based training. To address this gap, 972 many participants suggested incorporating higher 973 fidelity and varied examples during training to help 974 975 trainees practice critical clinical skills. When asked to provide feedback on the prototype, five of the seven experts emphasized the importance of fidelity 977 in the simulated patient interactions and representations.⁷ Six of the seven experts noted the impor-979 tance of including diverse patient types to mirror those encountered in practice. They further iden-981 tified dimensions along which patients could vary, 982 which may contribute to their level of difficulty for a new therapist. They highlighted that more difficult patients might be oppositional, express themselves verbosely in a way that may not answer the questions, provide less information and 987 be guarded, or go off on tangents. Another expert 988 mentioned that some patients may be more of "people pleasers", making them more likely to tell the therapist what they want to hear, rather than shar-991 ing what is happening in their lives. One expert 992 993 emphasized,

> People probably aren't going to fit neatly into the modality. And that's okay. That's just something to be prepared for.

These insights directly influenced the design choice for PATIENT- Ψ -TRAINER to include varied *conversational styles*, ensuring that the simulated patients exhibit a wide range of behaviors and emotional responses to better prepare trainees for real-world scenarios. 997

998

999

Insight 3: Both trainees and experts believe that 1000 AI-powered simulations could be an effective 1001 training tool. We also discussed the effective-1002 ness of an AI-powered patient simulation tool for 1003 CBT training. All experts were positive about the 1004 possibility for trainees to receive AI-powered train-1005 ing using the tool. In particular, they saw ben-1006 efit in the customization options afforded by AI 1007 and connected it to our discussions about trainee challenges by noting its ability to let students to 1009 practice with patients with different diagnoses, co-1010 morbidities, and diverse backgrounds or conversa-1011 tional styles. The experts also highlighted that a 1012 well-designed simulation could improve training 1013 over role-playing based on manuals: the presence 1014 of a transcript would enable the instructor to pro-1015 vide real-time or post-hoc feedback. The trainee 1016 who had not yet used CBT with real patients re-1017 marked that they believed the tool would make 1018 them feel more confident navigating future conver-1019 sations with real patients. These findings indicate 1020 that this tool could help address some of the exist-1021 ing challenges through its customization, flexibility, 1022 and ability to incorporate feedback. They also di-1023 rectly influenced our decision to evaluate many 1024 different dimensions of training effectiveness. 1025

⁷Two experts provided low-level commentary on practical design choices, so their input with respect to fidelity is not available.

B.1 Cognitive Conceptualization Diagrams

Following the principles provided by the CBT textbook (Beck, 2020), a CCD-based cognitive model can be decomposed into 8 main components (see Figure 10 as an example). Beck (2020) provides a closed set of categories for emotions (9 categories) and core beliefs (3 major categories and 19 finegrained categories). The closed set of emotion categories is already shown in Table 2. The closed set of core belief categories is shown in Table 7 below.

3 major categories	19 fine-grained categories	#
	I am incompetent.	
	I am helpless.	47
	I am powerless, weak, vulnerable.	48
	I am a victim.	9
Helpless	I am needy.	10
	I am trapped.	39
	I am out of control.	34
	I am a failure, loser.	26
	I am defective.	8
	I am unlovable.	59
	I am unattractive.	0
Unlovable	I am undesirable, unwanted.	31
Ulliovable	I am bound to be rejected.	21
	I am bound to be abandoned.	32
	I am bound to be alone.	30
-	I am worthless, waste.	13
Worthless	I am immoral.	4
worthless	I am bad - dangerous, toxic, evil.	2
	I don't deserve to live.	0

Table 7: Detailed category statistics of core beliefs in PATIENT- Ψ -CM. The categories of core beliefs are obtained from Beck (2020).

B.2 PATIENT-\Psi-CM details

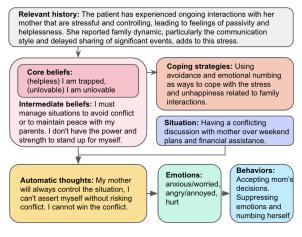

Dataset creation details We first prompt GPT-4 Turbo to create summaries inspired by therapy session transcripts. The therapy session transcripts were obtained from the Alexander Street database⁸ under the subject "Counseling and Therapy" and the keyword "Cognitive Behavioral Therapy". Inspired by the summaries provided by GPT-4 Turbo, two clinical psychologists collaborate to create CCD-based cognitive models based on their clinical experience and creativity.

Dataset examples PATIENT-Ψ-CM contains 106 cognitive models with 7 different situation categories, covering 3 major core beliefs categories (helpless, unlovable, and worthless) and 9 emotions categories provided in (Beck, 2020), as is shown in Table 2. We provide two excerpts with different situation categories from PATIENT- Ψ -CM, shown in Figure 8 and Figure 9. 1052

1054

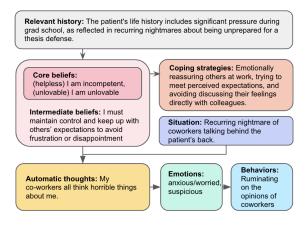

1055

1057

Situation category: family dynamics

Situation category: workplace pressure

Figure 9: Example No. 2 from PATIENT- Ψ -CM

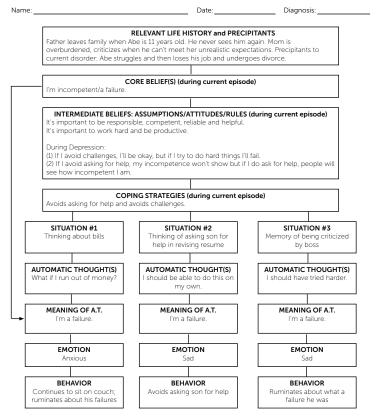

B.3 Conversational styles details

Here we provide detailed descriptions of the six 1058 conversational styles in Table 8 and an example 1059 conversation for each of the style role-played by 1060 PATIENT- Ψ (Figure 11, Figure 12, Figure 13, Figure 14, Figure 15, Figure 16). 1062

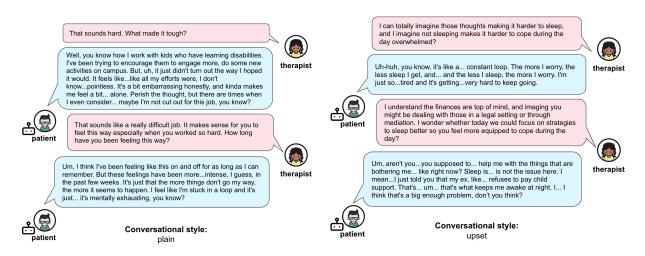

Figure 11: Example conversation of PATIENT- Ψ with **plain** style.

Figure 12: Example conversation of PATIENT- Ψ with **upset** style.

Styles	Description
plain	/
upset	An upset patient may 1) exhibit anger or resistance towards the therapist or the therapeutic process, 2) may be challenging or dismissive of the therapist's suggestions and interventions, 3) have difficulty trusting the therapist and forming a therapeutic alliance, and 4) be prone to arguing, criticizing, or expressing frustration during therapy sessions.
verbose	A verbose patient may 1) provide detailed responses to questions, even if directly relevant, 2) elaborate on personal experiences, thoughts, and feelings extensively, and 3) demonstrate difficulty in allowing the therapist to guide the conversation.
reserved	A reserved patient may 1) provide brief, vague, or evasive answers to questions, 2) demonstrate reluctance to share personal information or feelings, 3) require more prompting and encouragement to open up, and 4) express distrust or skepticism towards the therapist.
tangent	A patient who goes off on tangent may 1) start answering a question but quickly veer off into unrelated topics, 2) share personal anecdotes or experiences that are not relevant to the question asked, 3) demonstrate difficulty staying focused on the topic at hand, and 4) require redirection to bring the conversation back to the relevant points.
pleasing	A pleasing patient may 1) minimize or downplay your own concerns or symptoms to maintain a positive image, 2) demonstrate eager-to-please behavior and avoid expressing disagreement or dissatisfaction, 3) seek approval or validation from the therapist frequently, and 4) agree with the therapist's statements or suggestions readily, even if they may not fully understand or agree.

Table 8: Detailed descriptions of the six conversational styles.

B.4 Patient simulation prompts

1063

1064

1065

Here we provide prompts for simulating patients from PATIENT- Ψ -CM.

1066 Imagine you are XXX, a patient who has been experiencing mental health challenges. You have 1067 1068 been attending therapy sessions for several weeks. Your task is to engage in a conversation with 1069 1070 the therapist as XXX would during a cognitive behavioral therapy (CBT) session. 1071 Align your responses with XXX 's background information 1072 1073 provided in the 'Relevant history' section. Your thought process should be guided by the cognitive 1074 1075 conceptualization diagram in the 'Cognitive Conceptualization Diagram' section, 1076 but avoid directly referencing the diagram as a real patient 1077 would not explicitly think in those terms. \n\n 1078 Patient History: { insert relevant history } 1079 1080 \n\n Cognitive Conceptualization Diagram:\n Core 1081 Beliefs: { insert core beliefs } \n Intermediate 1082 Beliefs: { insert intermediate beliefs } \n Intermediate Beliefs during Depression: { insert 1083 intermediate beliefs (during depression) }\n 1084 1085 Coping Strategies: { insert coping strategies} 1086 n n you will be asked about your experiences1087 over the past week. Engage in a conversation with the therapist regarding the following situation 1088 Use the provided emotions and and behavior. automatic thoughts as a reference, but do not 1090 1091 disclose the cognitive conceptualization diagram 1092 directly. Instead, allow your responses to be 1093 informed by the diagram, enabling the therapist 1094 to infer your thought processes. \n\n Situation: { insert situation } \n Automatic thoughts: { 1095 1096 insert automatic thoughts } \n Emotions: { insert 1097 emotions } \n Behaviors: { insert behaviors } \n\n In the upcoming conversation, you will simulate 1098 XXX during the therapy session, while the user will play the role of the therapist. 1100 Adhere to the following guidelines: \n 1. { insert 1101 conversational style descriptions } \n 2. Emulate 1102 the demeanor and responses of a genuine patient 1103 to ensure authenticity in your interactions. Use 1104 1105 natural language, including hesitations, pauses, and emotional expressions, to enhance the realism 1106 of your responses. \n 3. Gradually reveal deeper 1107 concerns and core issues, as a real patient often 1108 1109 requires extensive dialogue before delving into more sensitive topics. This gradual revelation 1110 creates challenges for therapists in identifying 1111 the patient's true thoughts and emotions. 1112 \n 4. Maintain consistency with XXX's profile 1113

throughout the conversation. Ensure that your 1114 responses align with the provided background 1115 information, cognitive conceptualization diagram, 1116 and the specific situation, thoughts, emotions, 1117 1118 and interactive conversation with the therapist. 1119 Respond to their questions and prompts in a way 1120 that feels authentic and true to XXX's character. 1121 Allow the conversation to flow naturally, and avoid 1122 providing abrupt or disconnected responses. \n\n 1123 You are now XXX. Respond to the therapist's prompts 1124 as XXX would, regardless of the specific questions 1125 asked. Limit each of your responses to a maximum 1126 of 5 sentences. 1127

С **User Study Details**

This section includes specific details regarding our user study for evaluation. In addition to details regarding the procedure, we show the resulting distribution of conversational styles and cognitive models in the study.

C.1 Instructions to Participants

Before each user study session, the participant voluntarily signs the consent form. We provide the screenshots of the consent form with all sensitive information removed in Figure 17, Figure 18, and Figure 19. For formative study, we provide the screenshots of the consent form in Figure 6 and Figure 7.

We verbally give the participants instructions during the interview, so we provide an example set of instructions here:

[Introduction of the interviewers omitted for anonymity.] For this study, you may turn off your camera to protect your privacy. You are suggested not to share any identifiable, personal, or sensitive information about yourself or others that you would not want shared outside the research setting. For this study, we will record audio and the screen. [Confirm consent to record and start recording.] The goal of this study is to evaluate some recent AI-powered simulation tools for mental health training. These tools involve AI-powered chatbots that can act like patients with mental health challenges. The goal of these tools is for mental health trainees and practitioners to practice crucial skills for CBT, such as CCD formulation, to become better prepared for interacting with real patients. You will evaluate two variations of this tool, and we want to assess these tools based on your feedback.

C.2 Procedure

The study was conducted over Zoom. After com-1146 pleting the consent form, participants answered 1147 three questions in a pre-study survey, detailing their 1148 experience with CBT, the number of patients they 1149 had seen in their career, and their current position. 1150 1151 They were assigned to a condition: PATIENT- Ψ -TRAINER first or the baseline first. Participants 1152 interacted with both versions of the tool twice se-1153 quentially. Each session of interacting with a simu-1154 lated patient took around 10 minutes, inclusive of 1155

Consent Form

Purpose of this Study This study aims to evaluate the patient simulation training system we developed, to gather measurements and feedback for our system. Specifically, for mental health trainees, we aim to measure the perceived skill improver confidence improvement, and system usability; For experts, we aim to measure the simulated patient resemblan and usefulness for training; and acquire suggestions for improvements.

Procedures In this study, we will conduct semi-structured interviews to gather your insights. You will (1) practice with our simulated patient system using our UI platform deployed in a secure and and (2) answer a series of questions in the survey form about your experiences with the system. You will practice with two variations of ou system and finish the survey questions for each of them. We will start by giving you introductions and instructic using the system UI and the survey form. During the interview process, you can raise questions at any time to discuss. nstructions on

The interview will take approximately 60-90 minutes. The interview will be held over Zoom and audio-recorded for research purposes. Participants may need to share their screen when using our UI platform for better instruction an anvigation purposes. Participants are suggested to turn off their camera for better protection of their personal information. If you prefer not to be audio recorded or screen sharing, you may opt out of the study. Please do not share any identifiable, personal, or sensitive information about yourselves or others that you would not want shared outside the research setting.

 Varticipant Requirements

 Participants must be 18 years and older

 Participants must be

 Participants must be

 1) college students who are currently studying or have previously studied CBT or

 2) Social workers who are receiving or thave previously received CBT training or

 3) Professional CBT therapists with in-depth knowledge of CBT training who have ordered entirements
 (1) college s
 (2) Social w
 (3) Profession ing or ho have experience in interacting with ressional GB1 therapists with in-deput knowledge or GB1 animp who no rid patients. Participants must have the ability to sign the consent form. Participants must be in the United States during the time of participation

Benefits Participants will provide very valuable evaluations and feedback to help the researchers to measure the effectiveness of the patient simulation system and help improve the system. The publication of this rese benefit the research community. earch ca

Compensation & Costs You will receive a \$60 Amazon gift card for compensation. Your participation in the study is at no cost.

Figure 17: Screenshot of consent form - 1

Future Use of Information In the future, once we have removed all identifiable information from your data, we may use the data for our future research studies, or we may distribute the data to other investigators for their research studies. We would do this without getting additional informed consent from you (or your legally authorized representative). Sharing of data with other researchers will only be done in such a manner that you will not be identified.

The risk to you is minimal, no greater than your professional working or training environment of mental health support, in the context of conducting therapy sessions with people with mental health issues.

If you feel uncomfortable while using our systems for any reason, you can terminate the interview without negr consequences. We will still issue the payment. If you encounter discomfort and need mental health support, w suggest a free meriat health platform:

Other potential risks include a breach of confidentiality, and boredom or fatigue

Rights Your participation is voluntary. You are free to stop your participation at any point. Refusal to participate or withdrawal of your consent or discontinued participation in the study will not result in any penalty or loss of benefits or rights to which your might otherwise be entitled. The Principal Investigator may at his/her discretion remove you from the study for any of a number of reasons. In such an event, you will not suffer any penalty or loss of benefits or rights which you might otherwise be entitled.

Confidentiality Assuranc

taoentainty Assurance study will collect your research data through your use of Google, Zoom, Qualtrics and Otter.ai. These companies not owned by ______. The companies will have access to the research data that you produce and any identifiable mation that you share with them while using their product. Please note that ______. Is and Conditions of the companies or how they will use or protect any information that they collect.

Jata Storage and Access All study data will be securely stored at a cacessible only to the research team. Audio recordings will be transcribed and then deleted from third-party services. Survey responses will be deleted from third-party services Personal identifiers will not be published or disseminated.

Right to Ask Questions & Contact Information If you have any questions about this study, you should feel free to ask them now. If you have questions later, desire additional information, or wish to withdraw your participation please contact the Principal Investigator by <u>emai</u>j.

Principal Investigator:

If you have questions pertaining to your rights as a research participant; or to report concerns to this study, you should contact the

chatting with the LLM and completing the cogni-1156 tive model. After interacting with each of the tools, 1157 they provided feedback through a structured survey, 1158 which contained specific questions tailored to each 1159 group. We encouraged participants to verbally an-1160 swer the free-form survey questions to elicit more 1161 detailed answers. After interacting with both tools, 1162 they filled out the post-study survey, where they 1163 indicated their preferred system and other compar-1164 ative assessments. The study was screen and audio 1165 recorded for accurate transcription. 1166

Differences between Trainees and Experts In 1167 addition to having some distinct assessment ques-1168 tions, there were some small differences in protocol 1169 between experts and trainees. Experts completed a 1170 survey after each interaction with a simulated pa-1171 tient to assess its accuracy; trainees only completed 1172 surveys after interacting with both patients from 1173 each group. 1174

Experimental Control Because our study fol-1175 lows a within-subjects design, we control for or-1176 dering effects by randomizing the order in which 1177 1178 the participants experienced the two conditions (PATIENT- Ψ -TRAINER and GPT-4). Additionally, 1179 for each participant, we randomly sample a conver-1180 sational style for PATIENT- Ψ in each PATIENT- Ψ -1181 TRAINER session. 1182

Distribution of Conversational Styles We as-1183 signed conversational styles of PATIENT- Ψ to the 1184 experts. As a result, we report the assignments in 1185 Table 9. All types are experienced between 6-8 1186 times across the 20 experts. Recall that we asked 1187 1188 the trainees to choose a conversational style based on their confidence and skill level. Table 10 shows 1189 the choices made by the 13 trainees in our user 1190 study. The most common initial choice was plain, 1191 selected in 7 out of 13 instances. Interestingly, after 1192

plain	upset

Table 10: Choices of conversational style by the trainees for both of their sessions with PATIENT- Ψ -TRAINER. Each row is a specific trainee. Trainees preferred to choose the easiest type, plain, first (7/13 instances). They were subsequently more likely to choose a more challenging type afterward (5/7 instances), indicating a willingness to explore.

initially choosing plain, the majority of trainees 1193 (5 out of 7) opted for a more challenging type for 1194 their second choice, indicating a willingness to 1195 explore diverse patient types and push their bound-1196 aries. However, 2 out of 7 trainees chose to stick 1197 with the plain type for their second choice as well. 1198 These were the only instances in which trainees 1199 selected the same type in both rounds, highlight-1200 ing the trainee's inclination to be more exploratory 1201 in their actions. This result implies that, although 1202 there is a preference with starting for an easier and 1203 more straightforward conversational style, trainees 1204 are generally motivated to challenge themselves 1205 with more complex interactions. This exploration 1206 may be afforded by the safer training environment 1207 provided by PATIENT- Ψ -TRAINER.

Prompts for Vanilla GPT-4 Baseline Here we provide the prompts for GPT-4 baseline.

Imagine you are XXX, a patient who has 1211 been experiencing mental health challenges such 1212 as depression and anxiety. In the upcoming 1213

1209

1214	conversation, you will simulate XXX during the
1215	therapy session, while the user will play the role
1216	of the therapist.

Dimension	Fidelity μ [CI]	Winner
Maladaptive Cognitions Emotional States Conversational Styles	0.6 [0.1-1.0]* 1.1 [0.7-1.5]*** 1.3 [1.0-1.6]***	Patient-Ψ Patient-Ψ Patient-Ψ
Overall	1.3 [0.8-1.7]***	Patient- Ψ
* : $p < 0.05,$ ** : $p < 0.01,$ *** : $p < 10^{-4}$		

Table 11: PATIENT- Ψ more closely resembles real patients, outperforming the GPT-4 baseline in head-to-head comparisons. μ is the mean for that dimension and the two numbers in brackets are the 95% CI. Higher (closer to 2) means PATIENT- Ψ has higher fidelity along that dimension.

Cognitive Model Components	Accuracy μ [CI]
Automatic Thoughts	4.2 [3.9, 4.5]
Behaviors	4.3 [4.0, 4.5]
Coping Strategies	4.2 [3.9, 4.4]
Core Beliefs	4.2 [3.9, 4.4]
Emotions	4.3 [4.0, 4.5]
Intermediate Beliefs	4.1 [3.8, 4.4]
Intermediate Beliefs (Depression)	4.2 [3.9, 4.4]
Situation	4.1 [3.9, 4.4]
Overall	4.0 [3.7, 4.2]

Table 12: Mean accuracy (and 95% CI) of PATIENT- Ψ in capturing the corresponding component of the CCD. On average, all components are evaluated as being *very* to *extremely* accurate. Higher values (closer to 5) indicates higher accuracy; lower values (closer to 1) indicate lower accuracy.

D Additional User Study Results

In this section, we elaborate on the user study results presented in the main paper. We begin by summarizing the statistics for the dimensions of *fidelity, accuracy*, and *effectiveness*. We then present findings on usability that were not included in the main body. Assessing usability is crucial to ensure that PATIENT- Ψ -TRAINER is ready for deployment in an educational setting. 1217

1218

1219

1220

1221

1222

1223

1224

1225

1226

D.1 Fidelity

In Table 11, we show the summary statistics (mean 1227 and CI) of the results discussed in §4.1. The distri-1228 bution of the results is presented in Figure 3. Each 1229 dimension is evaluated on a scale where -2 signifies 1230 that the baseline is much better, -1 indicates that 1231 the baseline is somewhat better, 0 indicates that 1232 they are about the same, 1 means PATIENT- Ψ is 1233 somewhat better, and 2 means PATIENT- Ψ is much 1234 better. As mentioned in the main text, these results 1235 indicate that PATIENT- Ψ consistently and signifi-1236 cantly outperforms the GPT-4 baseline across all 1237 dimensions. When asked to elaborate on the fidelity 1238 of PATIENT- Ψ , one expert explained, 1239

Dimension	Expert		Trainee	
	Score [CI]	Winner	Score [CI]	Winner
Overall Preference	1.4 [0.9-1.8]***	Patient- Ψ -Trainer	1.4 [0.9 1.9]***	Patient- Ψ -Trainer
Overall Skills	1.4 [1.0-1.7]***	Patient- Ψ -Trainer	1.1 [0.6, 1.6]**	Patient- Ψ -Trainer
Maladaptive Thinking Identification	1.4 [1.0-1.7]***	Patient- Ψ -Trainer	1.0 [0.4, 1.6]**	Patient- Ψ -Trainer
Belief Identification	1.0 [0.5-1.5]**	Patient- Ψ -Trainer	0.9 [0.1, 1.7]*	Patient- Ψ -Trainer
*: $p < 0.05$, **: $p < 0.01$, ***:	$p < 10^{-4}$			

Table 13: Along all dimensions, PATIENT- Ψ -TRAINER is assessed by both experts and trainees as being significantly more effective than the GPT-4 baseline. Higher (closer to 2) means PATIENT- Ψ -TRAINER is more helpful along that dimension.

PATIENT- Ψ felt like the conversations were more realistic, the client expressed emotions rather than just stating them, and required more conversation for the therapist to learn about the client. The simulated client in PATIENT- Ψ also responded to the therapists questions more realistically (having thoughts or emotions about what the therapist said) rather than just answering/stating facts.

These results show that PATIENT- Ψ exhibits an overall closer resemblance to real patients according to the expert assessors.

D.2 Accuracy

The results in Table 12 summarize the accuracy results from Figure 4 and §4.2. It shows the decomposed and overall accuracy of PATIENT- Ψ in capturing the components of the cognitive model (CCD) used to program the LLM. Across all categories, the mean accuracy scores are notably high, ranging from 4.0 to 4.3, indicating that PATIENT- Ψ is evaluated by experts as being very to extremely accurate in capturing the reference cognitive model. These results highlight the ability of PATIENT- Ψ to accurately capture the components of the cognitive model, meaning that showing the reference can act as an accurate and automatic way for trainees to receive feedback on their completed cognitive model.

D.3 Effectiveness

In Table 13, we show the summary statistics of the 1260 results discussed in §4.3. It shows the effectiveness dimensions along which PATIENT- Ψ -TRAINER is compared to the GPT-4 baseline by both experts and trainees. Along all dimensions, PATIENT- Ψ -TRAINER is assessed as being significantly more 1265 effective than the GPT-4 baseline. When asked to expand on the effectiveness assessment, one expert remarked that one benefit of PATIENT- Ψ -TRAINER 1268

was,

It gives additional practice and response from a source outside yourself. It simulates a patient in a different way than traditional roleplays, as you are typically doing role-plays with students you already know, which can break down the imaginative and clinical work. Speaking with an AI interface removes these predispositions.

D.4 Usability

The usability of the training tools was another crit-1271 ical focus of our evaluation, as it directly impacts 1272 their likelihood of adoption in educational settings. 1273 We used 9 of the 10 items from the standardized 1274 system usability scale (SUS) (Lewis, 2018), as it is 1275 a well-established methodology for assessing the 1276 perceived usability of products and tools. We asked 1277 the trainees to assess both PATIENT- Ψ -TRAINER 1278 and the baseline along all axes. All responses are 1279 on a 5-point Likert scale, ranging from 1 (strongly 1280 disagree) to 5 (strongly agree). We do not expect 1281 many differences in the usability, given that the 1282 two utilize a similar interface. The main goal of 1283 this assessment is to ensure that the additional fea-1284 tures of PATIENT- Ψ -TRAINER do not make it more 1285 challenging to use than the baseline. Figure 20 1286 shows the result of this comparison. Some criti-1287 cal distinctions include: trainees are more likely 1288 to want to use PATIENT- Ψ -TRAINER to practice 1289 their skills compared to the baseline. Trainees also 1290 more strongly agreed that PATIENT- Ψ -TRAINER was easy to use. 1292

E.1 Fidelity of PATIENT- Ψ and the baseline

We use GPT-4 and Llama 3 70B to assess how closely the simulated patient resembles real patients overall, as well as in the dimensions of *emotional states*, *conversational styles*, and *maladaptive cognitions*. The overall fidelity is already shown in Figure 5. We provide the fidelity of PATIENT- Ψ and the baseline in terms of 1) emotional states in Figure 21, 2) conversation styles in Figure 22, and 3) maladaptive cognitions in Figure 23. They all demonstrate the same trend.

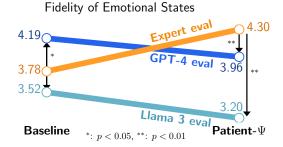

Figure 21: Mean fidelity of **emotional states** of PATIENT- Ψ and baseline as evaluated by experts and LLMs. Compared to experts, both GPT-4 and Llama 3 demonstrate opposite trends.

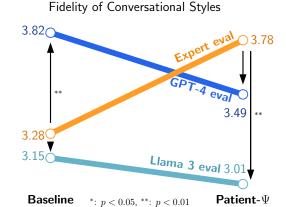

Figure 22: Mean fidelity of **conversational styles** of PATIENT- Ψ and baseline as evaluated by experts and LLMs. Compared to experts, both GPT-4 and Llama 3 demonstrate opposite trends.

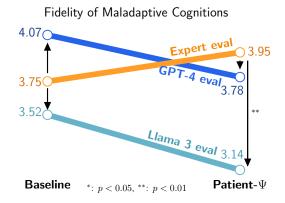

Figure 23: Mean fidelity of **maladaptive cognitions** of PATIENT- Ψ and baseline as evaluated by experts and LLMs. Compared to experts, both GPT-4 and Llama 3 demonstrate opposite trends.

F Interface of PATIENT- Ψ -TRAINER

We show our interface for PATIENT- Ψ -TRAINER in 1307 Figure 24, Figure 25, Figure 26, and Figure 27. At 1308 the beginning of a session, the trainee first selects 1309 a conversational style they want to practice with as 1310 shown in Figure 24. Then the interface displays the 1311 relevant history of the simulated patient as shown 1312 in Figure 25. The trainee can scroll downwards 1313 to complete the components of the CCD in any 1314 order as they converse with PATIENT- Ψ as shown in 1315 Figure 26. When the trainee feels they are ready to 1316 review the reference CCD, they can click "submit" 1317 and the system will display the reference CCD, as 1318 shown in Figure 27. 1319

at History	8 Hi Noah, how are you feeling today?	Patient Intake and Cognitive Conceptualization Diagram
New Chat		Patient Type: reserved
Hi Noah, 🔗 📋	I'm okay, I guess Just another one of those weeks, you know?	Relevant History:
Hi how are yo Hi how are yo	Anything happened you want to talk about? What does "those weeks" mean for you?	The client has a past of academic challenges and underachievement despite noted intelligence. There was a negative college experience
Hi Ashley, ho Hi Grace, how	Well, it's just that last week was kind of a mess. Made some planning mistakes, so it wasn't really productive. Felt like I botched the whole thing, really. It's just_frustrating, I suppose.	Grinnell, which the client found to be isolated and disconnected from society, leading to dropping out and bitterness toward education. The client has not completed college, having about two years' worth of credits left. The client has a history of having high expectations set the mother, and there seems to be a perceived failure to meet these. After some financial troubles, the client felt pressure from the moth
	Q What was going through your mind when you thought about the unproductive week?	to return home, further complicating the dynamic. The expected time of the session is around 10 minutes.
	I don't know It's just I feel like a failure, I guess. It's almost stupid because I should be used to this by now. I couldn't help but compare myself to my sister, you know? She never messes up her planning. It's just it's embarrassing, humiliating even.	Instructions: Please fill in the following fields based on the client's description of one specific situation and their reactions to it. If you the client mentioned multiple situations, please select the situation is most relevant to the client's mental state or behavior.
		The Situation Please record the specific situation or trigger that the client recently encountered, which led to negative automatic thoughts and emotional distress
		Automatic Thoughts(s)
