Parameter-Efficient Fine-Tuning of LLaMA for the Clinical Domain

Anonymous ACL submission

Abstract

 Adapting pretrained language models to novel domains, such as clinical applications, tradi- tionally involves retraining their entire set of parameters. Parameter-Efficient Fine-Tuning (PEFT) techniques for fine-tuning language models significantly reduce computational requirements by selectively fine-tuning small subsets of parameters. In this study, we propose a two-step PEFT framework and evaluate it in the clinical domain. Our approach combines a specialised PEFT adapter layer designed for clinical domain adaptation with another adapter specialised for downstream tasks. We evaluate the framework on multiple clinical outcome prediction datasets, comparing it to clinically trained language models. Our framework achieves a better AUROC score averaged across all clinical downstream tasks compared to clinical language models. In particular, we observe large improvements of 4-5% AUROC in large-scale multilabel classification tasks, such as diagnoses and procedures classification. To our knowledge, this study is the first to provide an extensive empirical analysis of the interplay between PEFT techniques and domain adaptation in an important real-world domain of clini- cal applications. The code is accessible via 029 https://anonymous.4open.science/r/clinical peft-**030** [03B4.](https://anonymous.4open.science/r/clinical_peft-03B4)

031 1 Introduction

 Large Language Models (LLMs) have consistently achieved state-of-the-art performance across vari- ous NLP tasks. However, while these models ex- hibit impressive generalisation abilities, they often struggle to perform in specialised domains such as clinical applications, primarily due to the absence of domain-specific knowledge. The complexity of medical terminology and the presence of incom- plete sentences in clinical notes contribute to this challenge [\(Lehman and Johnson,](#page-9-0) [2023\)](#page-9-0). Unfor-tunately, studies have indicated that even LLMs

Figure 1: An illustration of the proposed two-step PEFT framework. Clinical LLaMA-LoRA fine-tunes the pretrained LLaMA to the clinical domain. Downstream LLaMA-LoRA further fine-tunes the domain-adapted model to downstream clinical tasks.

pretrained with datasets comprising biomedical **043** publications still exhibit suboptimal performance **044** when applied to downstream clinical applications, $\qquad \qquad 045$ particularly when compared to LLMs pretrained **046** with clinical notes [\(Alsentzer et al.,](#page-8-0) [2019;](#page-8-0) [Li et al.,](#page-9-1) 047 [2022;](#page-9-1) [Yang et al.,](#page-10-0) [2022\)](#page-10-0). This observation suggests **048** that there are intrinsic nuances specific to the clini- **049** cal context that can only be effectively captured if **050** LLMs undergo pretraining using clinical datasets. **051**

The current approach of adapting pretrained **052** LLMs to the clinical domain typically involves **053** [fi](#page-8-0)ne-tuning the entire model parameters [\(Alsentzer](#page-8-0) **054** [et al.,](#page-8-0) [2019;](#page-8-0) [Peng et al.,](#page-10-1) [2019;](#page-10-1) [van Aken et al.,](#page-10-2) [2021;](#page-10-2) **055** [Michalopoulos et al.,](#page-9-2) [2021;](#page-9-2) [Lehman and Johnson,](#page-9-0) **056** [2023\)](#page-9-0). However, due to the rapid increase in the **057** size of LLMs, such a practice demands extensive **058** computational resources, which may not be readily **059** accessible to all researchers. Consequently, this **060** challenge will further exacerbate the disparity be- **061** tween the resource-rich and resource-constrained **062** research institutions [\(Ruder et al.,](#page-10-3) [2022\)](#page-10-3). **063**

To address the substantial computational de- **064** mands, studies have proposed various Parameter- **065**

1

 Efficient Fine-Tuning (PEFT) techniques. These techniques present a practical solution by fine- tuning a small subset of additional parameters while keeping the remaining pretrained parameters fixed. As a result, this strategy significantly alle- viates the computational burden while achieving comparable performance to that of full fine-tuning.

 In this study, we propose a two-step PEFT frame- work (see Figure [1\)](#page-0-0). Firstly, we introduce Clinical 075 LLaMA-LoRA, a Low-Rank Adaptation (LoRA, **[Hu et al.,](#page-9-3) [2022\)](#page-9-3) PEFT adapter built upon the open-** source Large Language Model Meta AI (LLaMA) **[\(Touvron et al.,](#page-10-4) [2023\)](#page-10-4). Then, we introduce Down-** stream LLaMA-LoRA, which is trained on top of the pretrained Clinical LLaMA-LoRA. Down- stream LLaMA-LoRA is specifically designed for clinical downstream tasks. The fusion of the two adapters achieves better performance in clini- cal NLP downstream tasks compared to clinically trained LLMs while considerably reducing the com- putational requirements. This study presents the following contributions:

- **088** We introduce Clinical LLaMA-LoRA, a PEFT-**089** adapted version of the LLaMA model tailored **090** specifically for the clinical domain.
- **191** We provide comparisons of multiple PEFT tech-**092** niques in terms of language modelling perfor-**093** mance based on perplexity score, shedding light **094** on the optimal PEFT techniques for the clinical **095** domain-adaptive pretraining.
- **196** We introduce Downstream LLaMA-LoRA, built **097** on top of Clinical LLaMA-LoRA and tailored **098** specifically for the clinical downstream tasks.
- **099** We evaluate the proposed mixture of Clinical **100** LLaMA-LoRA and Downstream LLaMA-LoRA **101** on downstream clinical datasets and tasks. Our **102** proposed framework showcases improvements in **103** AUROC scores over the existing clinical LLMs.

¹⁰⁴ 2 Background

105 2.1 Biomedical Large Language Models

 General-domain LLMs continue to face challenges when confronted with domain-specific tasks. The complexity associated with the requisite domain knowledge is recognised as a significant fac- tor [\(Ling et al.,](#page-9-4) [2023\)](#page-9-4), particularly within the biomedical domain. Consequently, numerous stud- ies have attempted to adapt LLMs specifically for the biomedical domain.

An early example of such adaptation is 114 BioBERT [\(Lee et al.,](#page-9-5) [2019\)](#page-9-5), which was pretrained 115 using biomedical research articles from PubMed **116** and PubMed Central. This adaptation has shown **117** improved performance across various biomedi- **118** cal NLP tasks. Recognising the significance of **119** biomedical-specific vocabularies, [Gu et al.](#page-8-1) [\(2022\)](#page-8-1) **120** proposed PubMedBERT, which is pretrained on **121** biomedical data from scratch and initialised the **122** model vocabulary with the biomedical corpus. The **123** growing interest in biomedical NLP research has **124** led to the adaptation of even larger models to the **125** biomedical domain [\(Luo et al.,](#page-9-6) [2022;](#page-9-6) [Singhal et al.,](#page-10-5) **126** [2022;](#page-10-5) [Wu et al.,](#page-10-6) [2023;](#page-10-6) [Singhal et al.,](#page-10-7) [2023\)](#page-10-7) **127**

While these biomedical LLMs have demon- **128** strated advancements in various biomedical NLP **129** benchmarking tasks, studies have revealed that **130** clinical LLMs still outperform their biomedical **131** counterparts in numerous clinical downstream **132** tasks [\(Alsentzer et al.,](#page-8-0) [2019;](#page-8-0) [Yang et al.,](#page-10-0) [2022;](#page-10-0) **133** [Li et al.,](#page-9-1) [2022;](#page-9-1) [Lehman and Johnson,](#page-9-0) [2023\)](#page-9-0). This **134** suggests that domain-adaptive pretraining using **135** clinical data is still the *de facto* protocol in adapt- **136** ing LLMs to the clinical domain. **137**

2.2 Clinical Large Language Models **138**

Clinical LLMs are often fine-tuned with clinical **139** data from an LLM that is already pretrained with **140** datasets that encompass broader topics. For in- **141** stance, Bio+ClinicalBERT [\(Alsentzer et al.,](#page-8-0) [2019\)](#page-8-0) 142 is domain-adaptively pretrained using clinical notes **143** from the Medical Information Mart for Intensive **144** Care (MIMIC)-III database [\(Johnson et al.,](#page-9-7) [2016\)](#page-9-7), **145** starting from a pretrained BioBERT [\(Lee et al.,](#page-9-5) 146 [2019\)](#page-9-5), which itself is pretrained on biomedical ar- **147** ticles. BlueBERT [\(Peng et al.,](#page-10-1) [2019\)](#page-10-1) is domain- **148** adaptively pretrained using PubMed abstracts and **149** [M](#page-8-2)IMIC-III clinical notes from a BERT model [\(De-](#page-8-2) **150** [vlin et al.,](#page-8-2) [2019\)](#page-8-2), that is pretrained with general- **151** [d](#page-9-0)omain texts. Similarly, Clinical-T5 [\(Lehman and](#page-9-0) **152** [Johnson,](#page-9-0) [2023\)](#page-9-0) is domain-adaptively pretrained us- **153** [i](#page-9-8)ng the union of MIMIC-III and MIMIC-IV [\(John-](#page-9-8) **154** [son et al.,](#page-9-8) [2023\)](#page-9-8) clinical notes from T5-base [\(Raffel](#page-10-8) **155** [et al.,](#page-10-8) [2020\)](#page-10-8), another general-domain LLM. **156**

All these studies share a common approach, 157 which is to fine-tune the entire model parameters. **158** With massive LLMs, this method has become cost- **159** prohibitive and inaccessible for many researchers. **160**

Figure 2: Frameworks of domain-adaptive and downstream fine-tuning to adapt a pretrained LLM from the general domain to the clinical domain. As opposed to a full fine-tuning process which can be prohibitively expensive (left), our approach leverages PEFT techniques to introduce a clinically-specialised adapter that is attached to a pretrained general LLM (right). Our proposed framework also introduces another clinical PEFT adapter trained on the downstream clinical tasks, such as clinical note classification.

161 2.3 Parameter-Efficient Fine-Tuning for **162** Large Language Models

Suppose that we have a pretrained LLM $P_{\Phi}(y|x)$; fine-tuning it can be effectively defined as find- ing the most appropriate parameter changes ∆Φ by optimising the fine-tuning objective. A con- ventional, full fine-tuning process means that the model needs to learn a ∆Φ whose dimension is equal to the entire parameters of the pretrained **LLM** $|\Delta \Phi| = |\Phi_0|$, which is computationally ex- pensive. PEFT techniques address this by tuning the *delta* ∆Φ, which corresponds to a very small fraction of additional trainable parameters during the fine-tuning process.

 Adapter tuning [\(Houlsby et al.,](#page-8-3) [2019\)](#page-8-3) is an early PEFT method that involves adding small additional parameters called *adapters* to each layer of the pre- trained model and strictly fine-tuning this small set of new parameters. LoRA [\(Hu et al.,](#page-9-3) [2022\)](#page-9-3) is another PEFT approach that trains low-rank ma- trices to represent the attention weights update of transformer-based models.

 Another group of PEFT approaches leverages [t](#page-9-9)he concept of prompting. Prefix Tuning [\(Li and](#page-9-9) [Liang,](#page-9-9) [2021\)](#page-9-9) optimises a sequence of continuous task-specific vectors, called a *prefix*, which are trainable parameters that do not correspond to real tokens. P-Tuning [\(Liu et al.,](#page-9-10) [2021b\)](#page-9-10) uses a similar strategy as Prefix tuning with a focus on text un- derstanding tasks, as opposed to generative tasks. Prompt tuning [\(Lester et al.,](#page-9-11) [2021\)](#page-9-11) simplifies Pre- fix tuning by introducing trainable tokens, called *soft prompts*, for each downstream task. [Liu et al.](#page-9-12) [\(2021a\)](#page-9-12) introduced P-tuning v2 which uses deep **194** prompt tuning to address the lack of performance **195** gain in the previous prompt tuning techniques. **196**

By fine-tuning a small fraction of additional pa- **197** rameters, all PEFT approaches alleviate the issue **198** of extensive computational resource requirements. **199**

2.4 Multi-step Adaptation **200**

Prior studies have explored the two-step adaptation 201 framework, although they have fundamental dif- **202** ferences from our proposed setup. For instance, **203** [Zhang et al.](#page-10-9) [\(2021\)](#page-10-9) introduced a multi-domain **204** unsupervised domain adaptation (UDA) with a **205** two-step strategy, involving domain-fusion train- **206** ing with Masked Language Model loss on a mixed **207** corpus, followed by task fine-tuning with a task- **208** specific loss on the domain corpus. More recently, **209** [Malik et al.](#page-9-13) [\(2023\)](#page-9-13) introduced UDApter which **210** utilises PEFT adapters to do efficient UDA. How- **211** ever, unsupervised domain matching techniques **212** such as UDApter rely on restrictive assumptions **213** about the underlying data distributions that are of- **214** ten unsatisfied in real-world scenarios [\(Li et al.,](#page-9-14) **215** [2020\)](#page-9-14). In our study, we experiment with the clin- **216** ical domain as the target domain that is not avail- **217** able in the LLM's initial pretraining. Consequently, **218** significant discrepancies exist between the distribu- **219** tions of the source and target domains. Leveraging **220** the amount of available clinical notes, we adopt **221** a self-supervised learning paradigm by continu- **222** ally pretraining the LLMs within the target domain **223** rather than relying on the UDA paradigm. **224**

Our approach shares theoretical similarities with **225** the multi-step continual pretraining approach, pro- **226** posed by [Gururangan et al.](#page-8-4) [\(2020\)](#page-8-4), which proposes domain- and task-adaptive pretraining. However, the main difference between our proposed approach and [Gururangan et al.](#page-8-4) [\(2020\)](#page-8-4) is in the discrepancy [b](#page-8-4)etween the source and the target domains. [Gu-](#page-8-4) [rurangan et al.](#page-8-4) [\(2020\)](#page-8-4) experimented with adapt- ing general-domain LLMs to domains encountered during their initial pretraining, such as news and biomedical domains. On the other hand, we experi- ment with the clinical domain which is entirely ab- sent from the LLMs' initial pretraining due to legal constraints which restrict access to sensitive clin- ical notes. On top of that, adapting to the clinical domain poses a bigger challenge due to the com- plexity of medical terminology and the presence of incomplete sentences [\(Lehman et al.,](#page-9-15) [2023\)](#page-9-15).

²⁴³ 3 Methodology

244 3.1 Problem Statement

245 Figure [2](#page-2-0) shows the comparison between the current **246** and proposed problem definitions. The general **247** problem can be decomposed into two stages:

248 Domain-adaptive Pretraining. Given a pre-249 trained general LLM $P_{\Phi}(y|x)$ with its parameters 250 Φ and a training dataset $\mathcal{Z} = \{(x_i, y_i)\}_{i=1,\dots,N}$. To **251** adapt to the new domain, the model needs to update 252 its weight iteratively from its pretrained state Φ_0 253 to $\Phi = \Phi_0 + \Delta \Phi$. This process of maximising the **254** objective function can be defined as:

$$
\arg\!\max_{\Phi} \sum_{(x,y)\in\mathcal{Z}} \sum_{t=1}^{|y|} \log \left(P_{\Phi} \left(y_t \mid x, y_{< t} \right) \right)
$$

 In the current paradigm, a full fine-tuning process means that the model needs to learn a ∆Φ whose di- mension is equal to the entire pretrained parameters $|\Delta \Phi| = |\Phi_0|$, which is computationally expensive.

 In the proposed paradigm, we tune only small **additional parameters** θ **such that** $\Phi = \Phi_0 + \Delta \Phi(\theta)$ whose dimension is very small compared to the **original parameters** $|\theta| \ll |\Phi_0|$. Thus, the training objective can be redefined as:

$$
\underset{\theta}{\operatorname{argmax}} \sum_{(x,y)\in\mathcal{Z}} \sum_{t=1}^{|y|} \log \left(P_{\Phi_0 + \Delta\Phi(\theta)} \left(y_t \mid x, y_{< t} \right) \right)
$$

 In the current paradigm, the outcome of domain- adaptive pretraining would be a clinically-adapted LLM. While in the proposed paradigm, the out- come would be the clinical PEFT component, which can be combined with the untouched pre-trained general LLM for downstream applications.

265

Downstream Fine-tuning. In the current **272** paradigm, the pretrained clinical LLM is fine- **273** tuned to the downstream tasks, such as document **274** classification tasks. Suppose that we have a **275** pretrained clinical LLM $P_{\Phi,\Theta}$ with its domain- **276** adapted parameters Φ and a newly initialised **277** classifier layer Θ, as well as a training dataset **278** $\mathcal{Z} = \{(x_i, y_i)\}_{i=1,\dots,N}$. We want to maximise a 279 specific loss function, such as a cross-entropy loss: **280**

$$
\underset{\Phi,\Theta}{\operatorname{argmax}} \frac{1}{N} \sum_{i=1}^{N} y_i \log \left(P_{\Phi,\Theta} \left(x_i \right) \right) \tag{281}
$$

In contrast, in the proposed paradigm, the fine- **282** tuning process only updates the small additional **283** parameters $\Delta \Phi(\theta)$ and the classifier head Θ : **284**

$$
\underset{\theta,\Theta}{\operatorname{argmax}} \frac{1}{N} \sum_{i=1}^{N} y_i \log \left(P_{\Phi + \Delta\Phi(\theta),\Theta} \left(x_i \right) \right) \tag{285}
$$

In fact, we can also decompose the fine-tuning into **286** an additional "delta-updating" process: **287**

$$
\underset{\theta,\phi,\Theta}{\operatorname{argmax}} \frac{1}{N} \sum_{i=1}^{N} y_i \log \left(P_{\Phi + \Delta\Phi(\theta) + \Delta\Phi(\phi),\Theta} \left(x_i \right) \right) \tag{288}
$$

Similar to the Domain-adaptive Pretraining stage, **289** the dimensions of the additional parameters θ and ϕ 290 are very small compared to the original parameters. **291** By updating only the additional parameters and **292** the classifier head, the proposed paradigm reduces **293** the computational requirements, making it more **294** efficient and feasible, especially for clinical settings **295** that are often resource-constrained. **296**

3.2 Two-step LLaMA-LoRA **297**

In this study, we propose a two-step PEFT frame- **298** work (as shown on the right-hand side of Figure [2\)](#page-2-0). 299 Firstly, we introduce Clinical LLaMA-LoRA, a 300 LoRA adapter built upon LLaMA [\(Touvron et al.,](#page-10-4) **301** [2023\)](#page-10-4) that is adapted to the clinical domain. Sec- **302** ondly, we introduce Downstream LLaMA-LoRA, **303** which is trained on top of the pretrained Clinical 304 LLaMA-LoRA and is specifically adapted to the **305** downstream tasks. 306

LLaMA models In this study, we evaluate two **307** LLaMA models; the 7 billion parameters version **308** of LLaMA [\(Touvron et al.,](#page-10-4) [2023\)](#page-10-4) and the 7 bil- **309** lion parameters version of PMC-LLaMA[\(Wu et al.,](#page-10-6) **310** [2023\)](#page-10-6). LLaMA was pretrained with an array of **311** texts from multiple sources, such as English Com- **312** monCrawl, Wikipedia, ArXiv, and C4 [\(Raffel et al.,](#page-10-8) **313**

		Dataset # Class Multilabel # Train		# Valid	# Test
LOS		х	30.421	4.391	8.797
MOR	$\mathcal{D}_{\mathcal{A}}$	х	33.954	4.908	9.822
PMV	っ	х	5.666	707	706
DIAG	1,266	✓	33.994	4.918	9.829
PROC	711		30,030	4.357	8.681

Table 1: Statistics and types of downstream clinical document classification tasks: length of stay (LOS), mortality (MOR), prolonged mechanical ventilation (PMV), diagnoses (DIAG), and procedures (PROC).

314 [2020\)](#page-10-8). While, PMC-LLaMA is a domain-adapted **315** LLaMA model that was pretrained on 4.8 million **316** biomedical academic papers from PubMed Central.

 Domain-adaptive Pretraining: Clinical LLaMA- LoRA Clinical LLaMA-LoRA is trained using a combination of MIMIC-IV de-identified dis- charge summaries (331,794) and radiology reports (2,321,355), resulting in a collection of 2,653,149 individual clinical notes. We evaluate five PEFT techniques, which include *LoRA* [\(Hu et al.,](#page-9-3) [2022\)](#page-9-3), *Adaptation Prompt* [\(Zhang et al.,](#page-10-10) [2023\)](#page-10-10), *Prefix Tun- [i](#page-9-11)ng* [\(Li and Liang,](#page-9-9) [2021\)](#page-9-9), *Prompt Tuning* [\(Lester](#page-9-11) [et al.,](#page-9-11) [2021\)](#page-9-11), and *P-tuning* [\(Liu et al.,](#page-9-10) [2021b\)](#page-9-10).

 Our approach follows the autoregressive lan- guage modelling pretraining objective employed in the original LLaMA training. To ensure compatibil- ity with available computational resources, we use fixed model hyperparameters that allow us to fit the LLM into a single NVIDIA A100-80GB GPU (see Appendix [A.1\)](#page-11-0). We optimise the hyperparameters specific to each PEFT method using Gaussian Pro- cess regression for Bayesian Optimisation [\(Frazier,](#page-8-5) 2018 2018 ¹ with a maximum of 20 trials. The detailed hyperparameters search space can be found in Ap- pendix [A.2.](#page-11-1) During this stage, we evaluate the perplexity scores of the LLM variants.

340 Downstream Fine-tuning: Downstream **341** LLaMA-LoRA We fine-tune the Clinical **342** LLaMA-LoRA and Downstream LLaMA-LoRA **343** to clinical document classification tasks:

- **344** Prolonged mechanical ventilation (PMV): a **345** binary classification task to predict whether a **346** patient will require mechanical ventilation for **347** more than seven days [\(Huang et al.,](#page-9-16) [2020;](#page-9-16) [Naik](#page-9-17) **348** [et al.,](#page-9-17) [2022\)](#page-9-17).
- **349** In-hospital mortality (MOR): a binary classifi-**350** cation task to predict whether a patient will sur-

vive during their hospital stay [\(van Aken et al.,](#page-10-2) **351** [2021;](#page-10-2) [Naik et al.,](#page-9-17) [2022\)](#page-9-17). **352**

- Length of stay (LOS): a multiclass classification **3** task to predict the length of a patient's hospital 3 stay, categorised into four time-bins: less than 35 three days, three to seven days, one to two weeks, **356** and more than two weeks [\(van Aken et al.,](#page-10-2) [2021;](#page-10-2) [Naik et al.,](#page-9-17) [2022\)](#page-9-17).
- **Diagnoses (DIAG):** a large-scale multilabel classification task to predict the differential diagnoses 3 of a patient, represented by simplified ICD-9 di- **361** agnosis codes [\(van Aken et al.,](#page-10-2) [2021\)](#page-10-2). **362**
- **Procedures (PROC):** a large-scale multilabel 3 classification task to predict the treatments ad- **364** ministered to a patient, represented by simplified 3 ICD-9 procedure codes [\(van Aken et al.,](#page-10-2) [2021\)](#page-10-2).

The label and split statistics of each dataset can be found in Table [1.](#page-4-1)

During this downstream fine-tuning process, we use fixed model hyperparameters to ensure **370** compatibility with the available computational re- 37³ sources, a single NVIDIA A100-80GB GPU (see $\frac{3}{2}$ Appendix [B.1\)](#page-11-2). We optimise the hyperparameters **3** specific to each PEFT method using Gaussian Pro- 37444 cess regression for Bayesian Optimisation with a **375** maximum of 20 trials. The detailed hyperparame- 376³ ters search space of the PEFT method can be found **377** in Appendix [B.2.](#page-11-3) **378**

For evaluating the performance of the model on 3 these downstream tasks, we report the Area Under **3** the Receiver Operating Characteristic Curve (AU- **381** ROC) scores. Additionally, we report the macroaveraged AUROC score across all clinical tasks as **3** [c](#page-10-11)ommonly done in NLP benchmarking tasks [\(Wang](#page-10-11) 3 [et al.,](#page-10-11) [2019;](#page-10-11) [Peng et al.,](#page-10-1) [2019;](#page-10-1) [Gu et al.,](#page-8-1) [2022\)](#page-8-1). **385**

3.3 Baseline Models 3.3 Baseline Models

We selected baseline models that have undergone **3** a domain-adaptive pretraining process on clinical **388** notes (MIMIC-III). Thus, these baseline models $\frac{3}{8}$ have been designed to perform specifically on clin- 39 ical data, providing comparison points for evaluat- 39 ing our proposed approach of two-step adaptation **392** in downstream clinical NLP tasks. The baseline **393** models used in the evaluation are as follows: **394**

• Bio+ClinicalBERT [\(Alsentzer et al.,](#page-8-0) [2019\)](#page-8-0): **395** Bio+ClinicalBERT is pretrained on MIMIC-III **396** clinical notes. It is initialised from a biomedi- **397** cal language model called BioBERT [\(Lee et al.,](#page-9-5) **398** [2019\)](#page-9-5), which is pretrained on biomedical re- **399** search articles. **400**

¹ Specifically, we use the W&B Sweep APIs: [https://](https://docs.wandb.ai/guides/sweeps) docs.wandb.ai/guides/sweeps

- **401** BlueBERT [\(Peng et al.,](#page-10-1) [2019\)](#page-10-1): BlueBERT is pre-**402** trained on MIMIC-III clinical notes and PubMed **403** abstracts starting from the pretrained checkpoint **404** of BERT [\(Devlin et al.,](#page-8-2) [2019\)](#page-8-2), a general-domain **405** language model.
- **406** CORe [\(van Aken et al.,](#page-10-2) [2021\)](#page-10-2): CORe is pre-**407** trained on MIMIC-III clinical notes and biomed-**408** ical articles starting from the pretrained check-**409** point of BioBERT [\(Lee et al.,](#page-9-5) [2019\)](#page-9-5).

⁴¹⁷ 4 Results and Analysis

418 4.1 Domain-adaptive Pretraining

 The pretraining results can be found in Table [2.](#page-6-0) We employ PEFT techniques for domain-adaptive pretraining, requiring a significantly smaller num- ber of parameters ranging from just 0.001% to 0.24% of the original model parameters. This ap- proach substantially reduces the required compu- tational resources and training time. We perform a full-parameter domain-adaptive pretraining of LLaMA, referred to as Clinical LLaMA, using four NVIDIA A100-80GB GPUs which took 49.5 hours. Instead, PEFT techniques require less than 24 hours per epoch on average with only a single GPU with a comparable perplexity score.

 LoRA emerges as the best-performing PEFT method for both LLaMA and PMC-LLaMA in the clinical domain-adaptive pretraining, achieving the lowest perplexity scores of 2.244 and 2.404, respec- tively, which are very similar to Clinical LLaMA's perplexity score of 2.210. This pretrained LoRA is referred to as Clinical LLaMA-LoRA in the subsequent sections. The following experiments in downstream fine-tuning will utilise this pretrained Clinical LLaMA-LoRA.

442 4.2 Downstream Fine-tuning

443 From the downstream fine-tuning results shown **444** in Table [3,](#page-7-0) we can decompose the analysis into **445** multiple research questions:

 Can LoRA help fine-tune LLaMA from other domains (general and biomedical) to achieve higher AUROC scores in clinical tasks? We compare the results obtained by LLaMA and LLaMA + LoRA, as well as PMC-LLaMA and **450** PMC-LLaMA + LoRA, as presented in Table [3.](#page-7-0) **451** The obtained results consistently demonstrate im- **452** proved AUROC scores when utilising LoRA across **453** all tasks. The macro-averaged AUROC score of **454** LoRA-equipped LLaMA shows a notable 13.01% **455** increase when compared to the LLaMA-only base- **456** line. Similarly, LoRA-equipped PMC-LLaMA ex- **457** hibits a 12.19% improvement in macro-averaged **458** AUROC compared to the original PMC-LLaMA **459** Both LLaMA and PMC-LLaMA, when equipped **460** with LoRA, show significant AUROC score im-
 461 provements in all tasks except the PMV prediction **462** task, which is challenging for all model variants. **463**

Furthermore, the marginal difference in AUROC 464 scores between PMC-LLaMA and the general- **465** domain LLaMA may be attributed to two factors. **466** Firstly, the original LLaMA has been exposed to 467 biomedical concepts during its pretraining, reduc- **468** ing the need for domain-adaptive pretraining to the **469** biomedical domain. Secondly, clinical outcome **470** prediction requires an understanding of how to ap- **471** ply biomedical knowledge in an interconnected **472** manner to provide prognostic. We believe that **473** biomedical pretraining may not be sufficient in pro- **474** viding such practical knowledge. **475**

Can LoRA-equipped LLaMA and PMC- **476** LLaMA perform comparably in comparison to **477** clinically trained LMs? We compare the AU- **478** ROC scores obtained by the baseline models, and **479** LoRA-equipped LLaMA and PMC-LLaMA (see **480** Table [3\)](#page-7-0). Among the baseline models, UmlsBERT 481 performs the best with a macro-averaged AUROC **482** score of 72.70%. Compared to UmlsBERT, both **483** LLaMA and PMC-LLaMA underperform with **484** macro-averaged AUROC scores of 58.61% and **485** 60.51%, respectively. This finding highlights the **486** importance of clinical-specific fine-tuning. **487**

Significant improvements can be observed in **488** LoRA-equipped LLaMA and PMC-LLaMA, with **489** macro-averaged AUROC scores of 71.62% and **490** 72.70%, respectively, with noticeable improve- **491** ments in the diagnoses and procedures prediction **492** tasks. LoRA-equipped LLaMA achieves AUROC **493** scores of 78.37% and 87.49% in the diagnoses and **494** procedures prediction tasks, respectively, compared **495** to 72.08% and 78.32% for UmlsBERT. This repre- **496** sents improvements of 6.29% in diagnoses predic- **497** tion and 9.17% in procedures prediction. Improve- **498** ments are also observed in the results obtained **499** by LoRA-equipped PMC-LLaMA, outperforming **500**

Base Model	PEFT	Trainable Params	Train Ppl	Test Ppl	GPU	Train Time (h:m:s)
Clinical LLaMA	$\overline{}$	6.7B (100%)	1.811	2.210	4x80GB	49:26:38
LLaMA	LoRA	8.4M (0.12%)	1.858	2.244	1x80GB	21:37:42
	Adaptation Prompt	$1.2M(0.02\%)$	2.561	2.865	1x80GB	24:57:17
	Prefix Tuning	5.2M (0.08%)	2.815	2.748	1x80GB	20:11:07
	Prompt Tuning	61.4K(0.0009%)	4.846	4.007	1x80GB	23:27:28
	P-tuning	$16.1M(0.24\%)$	2.723	3.271	1x80GB	23:49:31
PMC-LLaMA	LoRA	$2.1M(0.03\%)$	1.938	2.404	1x80GB	21:32:59
	Adaptation Prompt	1.2M(0.018%)	2.374	2.867	1x80GB	23:33:10
	Prefix Tuning	$2.6M(0.04\%)$	1.789	2.848	1x80GB	20:13:10
	Prompt Tuning	$41K(0.0006\%)$	4.821	4.385	1x80GB	22:25:32
	P-tuning	$2.2M(0.03\%)$	3.491	4.572	1x80GB	22:28:15

Table 2: Domain-adaptive Pretraining results of LLaMA and PMC-LLaMA trained on MIMIC-IV clinical notes with a language modelling objective. Lower perplexity scores indicate better language modelling performance. The boldface row indicates the model with the lowest perplexity score from each base model variant.

501 UmlsBERT by 6.73% in diagnoses prediction and **502** 8.36% in procedures prediction.

 Can LLaMA and PMC-LLaMA with Clinical LLaMA-LoRA achieve higher AUROC scores than the clinically trained LMs? The domain- adaptive pretraining step yields the clinically- trained LoRA adapters for LLaMA and PMC- LLaMA, denoted as Clinical LLaMA-LoRA. We compare the results of Clinical LLaMA-LoRA- equipped LLaMA and PMC-LLaMA with the base- line models. We evaluate Clinical LLaMA-LoRA with and without fine-tuning, referred to as "Train-able" and "Frozen" respectively.

 The results indicate that Clinical LLaMA-LoRA- equipped LLaMA and PMC-LLaMA outperform the baseline models. LLaMA with a trainable Clin- ical LLaMA-LoRA achieves an AUROC score of 75.13%, surpassing UmlsBERT's score of 72.32%. PMC-LLaMA with a trainable Clinical LLaMA- LoRA achieves a lower AUROC score of 72.23%. LLaMA with a trainable Clinical LLaMA-LoRA also outperforms Clinical LLaMA which achieves an AUROC score of 58.86%.

 These findings indicate that the Clinical LLaMA- LoRA contributes to higher AUROC scores for LLaMA and PMC-LLaMA over clinically trained LLMs, while biomedical domain-adaptive pretrain- ing may not be necessary to improve the model's performance in the clinical settings.

 Can LLaMA and PMC-LLaMA with Clinical LLaMA-LoRA achieve higher AUROC scores than the other fine-tuning variants? We exam- ine the importance of the domain-adapted LoRA by comparing the results obtained by LLaMA and PMC-LLaMA equipped with Clinical LLaMA-

LoRA against the results of LLaMA and PMC- **536** LLaMA fine-tuning, both original and with LoRA. **537**

Firstly, we evaluate the frozen pretrained Clin- **538** ical LLaMA-LoRA. Both LLaMA and PMC- **539** LLaMA with frozen Clinical LLaMA-LoRA do **540** not exhibit a significant increase in performance **541** compared to the original fine-tuning. This indicates **542** that, despite the domain-adaptive pretraining, the **543** limited number of trainable parameters during the **544** downstream fine-tuning restricts the potential im- **545** provement that the model can achieve. A similar **546** finding can also be observed in the Clinical LLaMA **547** fine-tuning whose overall performance does not dif- **548** fer from the original fine-tuning. This finding is fur- **549** ther supported by the improvement in the AUROC **550** scores of LLaMA and PMC-LLaMA with trainable **551** Clinical LLaMA-LoRA, which achieve 75.13% **552** and 72.23% macro-averaged AUROC scores, re- **553** spectively. These represent substantial improve- **554** ments from the vanilla fine-tuning performance, **555** 58.61% and 60.51% AUROC scores. **556**

Can a downstream LoRA adapter improve the **557** AUROC scores of LLaMA and PMC-LLaMA **558** equipped with Clinical LLaMA-LoRA? By **559** considering Clinical LLaMA-LoRA as the "delta- **560** updating" outcome of the domain-adaptive pre- **561** training, we can view the downstream fine-tuning **562** process as an additional "delta-updating" step. **563** To investigate the impact of this approach, we **564** conduct experiments by adding a Downstream **565** LLaMA-LoRA to LLaMA and PMC-LLaMA **566** models that were already equipped with Clinical 567 LLaMA-LoRA. From Table [3,](#page-7-0) we can observe **568** that Downstream LLaMA-LoRA fails to improve **569** the performance of LLaMA and PMC-LLaMA **570** with frozen Clinical LLaMA-LoRA. On the other 571

Table 3: AUROC scores in clinical downstream document classification tasks. The macro-averaged AUROC score is calculated by taking the average of AUROC scores across all tasks. The boldface cell indicates the highest AUROC score in a column, the *row in italic* indicates the variant with the highest macro-averaged AUROC in its category. *+ LoRA* denotes applying LoRA on top of the pretrained LLM without domain-adaptive pretraining. *+ Clinical LLaMA-LoRA* denotes applying Clinical LLaMA-LoRA that is domain-adaptively pretrained on top of the pretrained LLM. *+ Downstream LLaMA-LoRA* denotes applying Downstream LLaMA-LoRA on top of the LLM + Clinical LLaMA-LoRA. *Frozen* means that the parameters are not trainable, while *Trainable* means that the parameters are trainable. ∗ Due to restricted computing resources, the fine-tunings of Clinical LLaMA, LLaMA, and PMC-LLaMA were constrained to only training the final classification layer.

 hand, improvement can be observed when adding Downstream LLaMA-LoRA to LLaMA with train- able Clinical LLaMA-LoRA. This combination of LLaMA with trainable Clinical LLaMA-LoRA and Downstream LLaMA-LoRA achieves the highest macro-averaged AUROC score of 76.07%. The macro-averaged AUROC score of Clinical LLaMA- LoRA was almost similar to that of PMC-LLaMA with LoRA, suggesting similar efficacy between Clinical LLaMA-LoRA and the full fine-tuning process that PMC-LLaMA has undergone. More- over, Clinical LLaMA-LoRA offers the advantage of reduced computational resources and training time, which is aligned with the requirements of practical implementation in clinical settings.

 Overall, our proposed method manages to achieve better performance in comparison to clini- cally trained models. We also provide a comparison with the state-of-the-art method of PMV, mortality, [a](#page-9-17)nd length of stay predictions, called BEEP [\(Naik](#page-9-17) [et al.,](#page-9-17) [2022\)](#page-9-17), which leverages retrieval augmen- tation method to provide more contextual infor- mation to the model during inference. The com- parison is only partial as BEEP models were not evaluated on the diagnosis and procedure predic-tion tasks. As shown in Appendix [C,](#page-11-4) our bestperforming model achieves a 70.03% averaged AU- **598** ROC score, which is slightly worse compared to **599** the best-performing BEEP model with 72.26% av- **600** eraged AUROC score. However, it is worth noting **601** that our proposed method and the state-of-the-art **602** method are complementary to each other. Hence, **603** future work may explore the possibility of combin- **604** ing the two approaches. **605**

5 Conclusions **⁶⁰⁶**

In this study, we propose a two-step PEFT frame- **607** work. We introduce Clinical LLaMA-LoRA, **608** a LoRA [\(Hu et al.,](#page-9-3) [2022\)](#page-9-3) adapter built upon **609** LLaMA [\(Touvron et al.,](#page-10-4) [2023\)](#page-10-4). Then, we intro- **610** duce Downstream LLaMA-LoRA, a task-specific **611** adapter that is trained on top of the pretrained **612** Clinical LLaMA-LoRA. The fusion of the two **613** adapters achieves an AUROC score of 76.07% **614** macro-averaged across all clinical NLP down- **615** stream tasks, which represents a 3.37% improve- 616 ment over the best-performing clinical LLM. Our **617** proposed framework achieves improvement in per- **618** formance while reducing the computational require- **619** ments, which is suited for clinical settings that are **620** often constrained by their computational power. **621**

⁶²² Limitations

 This study presents a two-step PEFT framework aimed at effectively adapting LLMs to diverse clin- ical downstream applications. However, the evalu- ation of our model was restricted to MIMIC-based datasets, which are constrained to English and ob- tained exclusively within the Commonwealth of Massachusetts, United States of America. Con- sequently, despite the promising efficacy demon- strated by our proposed method, it would have been advantageous to directly assess its performance across diverse hospital systems spanning other ge- ographical locations and languages. This would enable a more comprehensive understanding of its applicability and generalizability. However, it is essential to acknowledge that conducting such an analysis would require working within a trusted research environment and obtaining the necessary permissions to access the relevant datasets.

 It is crucial to recognise the restrictions imposed on accessing internal clinical datasets, as they limit our ability to evaluate the effectiveness of our approach across different care provider systems. Therefore, we encourage care providers to conduct internal experiments within their trusted research environment to ensure the efficacy of our proposed method within their specific use cases should they adopt this approach.

 Despite the demonstrated performance improve- ments, the proposed model may still be suscep- tible to spurious correlations. Predicting patient outcomes solely based on clinical notes presents significant challenges due to the other factors that may not be captured within those notes. For in- stance, the length of a patient's in-hospital stay is not solely correlated with their diagnoses and disease progression. Factors such as the patient's insurance status, which is not typically mentioned in clinical notes, can severely impact the duration of a patient's stay. Therefore, we encourage end users of such clinical LLMs to consider additional measures to ensure predictions that reflect a holistic view of the patient's situation, instead of relying solely on the predictions of LLMs.

⁶⁶⁶ Ethics Statement

 In this study, we use MIMIC-based datasets ob- tained after completing the necessary training. These datasets comply with de-identification stan- dards set by the Health Insurance Portability and Accountability Act (HIPAA) through data cleansing. Due to privacy concerns, we refrain from in- **672** cluding direct excerpts of the data in the paper. We **673** also refrain from publicly sharing the pretrained **674** checkpoints. 675

While our model demonstrates effectiveness, it is **676** important to acknowledge the risks associated with **677** relying solely on clinical outcome prediction mod- **678** els. There are crucial pieces of information that **679** can be found beyond the scope of clinical notes. **680** Considering the potential impact on patient health **681** outcomes, it is crucial to exercise caution when util- **682** ising these clinical LLMs. Therefore, we propose **683** that the PEFT adapter generated by our framework, **684** in conjunction with the pretrained LLM, should be **685** used as an aid rather than a replacement for trained **686** clinical professionals. **687**

938 A Hyperparameters for the **939 Domain-adaptive Pretraining**

940 A.1 Fixed Model Hyperparameters

Table 4: Fixed model hyperparameters for language modelling pretraining. These hyperparameters remain unchanged to fit LLaMA into a single GPU.

941 A.2 PEFT Hyperparameters Optimisation **942** Search Space

Table 5: The search space for PEFT Hyperparameters optimisation runs during the domain adaptation finetuning with language modelling objective. Each PEFT technique has a specific set of hyperparameters to tune, we selected the combination of hyperparameters which has the lowest perplexity score.

943 Specifically for Prompt Tuning, we use a com-**944** mon prompt initialisation text "Finish this clinical **945** note:".

⁹⁴⁶ B Hyperparameters for the Downstream **947 Fine-tuning**

948 B.1 Fixed Model Hyperparameters

Table 6: Fixed model hyperparameters for the clinical downstream fine-tuning. These hyperparameters remain unchanged to fit LLaMA into a single GPU.

B.2 PEFT Hyperparameters Optimisation **949** Search Space **950**

Table 7: The search space for PEFT Hyperparameters optimisation runs during the downstream fine-tuning. Each PEFT technique has a specific set of hyperparameters to tune, we selected the combination of hyperparameters which has the highest AUROC score.

C Comparison with BEEP [\(Naik et al.,](#page-9-17) **⁹⁵¹** [2022\)](#page-9-17) **⁹⁵²**

Table 8: AUROC scores in a subset of the clinical downstream document classification tasks. The macroaveraged AUROC score is calculated by taking the average of AUROC scores across this subset of tasks. The *row in italic* indicates the model variant with the highest macro-averaged AUROC.

We compared our method with the state-of-the-art **953** [c](#page-9-17)linical outcome prediction model, BEEP [\(Naik](#page-9-17) **954** [et al.,](#page-9-17) [2022\)](#page-9-17), which leverages a retrieval augmen- **955** tation technique to enhance the predictive capabil- **956** ities of clinical language models. A small caveat **957** is that BEEP focused on three downstream tasks: **958** prolonged mechanical ventilation, mortality, and **959** length of stay predictions. We selected the best- **960** performing solution from BEEP, UmlsBERT with **961** weighted voting retrieval augmentation, based on **962** the averaged AUROC score to compare with our **963** solution. While BEEP outperforms our approach, **964** particularly in the prediction of PMV, it is crucial to **965** emphasise that our method achieves its predictions **966** without relying on retrieval augmentation. Future **967** work may explore using retrieval augmentation on **968** top of our proposed method. **969**

D Training Configurations **970**

We use HuggingFace's Transformers [\(Wolf et al.,](#page-10-13) **971** [2020\)](#page-10-13) and PEFT [\(Mangrulkar et al.,](#page-9-18) [2022\)](#page-9-18) libraries **972** for the experiments. All LLaMA-based models are **973** trained on one NVIDIA A100-80GB GPU, while **974** the baseline models are trained on a single NVIDIA **975** GeForce GTX 1080 Ti-16GB GPU. **976**

E Artefacts

 The pretrained baseline models including BioClini- [c](#page-10-1)alBERT [\(Alsentzer et al.,](#page-8-0) [2019\)](#page-8-0), BlueBERT [\(Peng](#page-10-1) [et al.,](#page-10-1) [2019\)](#page-10-1), and CORe [\(van Aken et al.,](#page-10-2) [2021\)](#page-10-2) were released under the Creative Commons desig- nation CC0 1.0 Universal license, whereas Umls- BERT [\(Michalopoulos et al.,](#page-9-2) [2021\)](#page-9-2) was released under the MIT license. LLaMA [\(Touvron et al.,](#page-10-4) [2023\)](#page-10-4) was released under a noncommercial license.

 MIMIC-III and MIMIC-IV dataset was released under the PhysioNet Credentialed Health Data Li- cense 1.5.0 and can only be accessed after one fin- ishes the CITI Data or Specimens Only Research **training^{[2](#page-12-0)}.**
