METAKP: On-Demand Keyphrase Generation

Anonymous ACL submission

Abstract

 Traditional keyphrase prediction methods pre- dict a single set of keyphrases per document, failing to cater to the diverse needs of users and downstream applications. To bridge the gap, we introduce on-demand keyphrase generation, a novel paradigm that requires keyphrases that conform to specific high-level goals or intents. For this task, we present METAKP, a large- scale benchmark comprising four datasets, 7500 documents, and 3760 goals across news and biomedical domains with human-annotated keyphrases. Leveraging METAKP, we design both supervised and unsupervised methods, in- cluding a multi-task fine-tuning approach and a self-consistency prompting method with large language models. The results highlight the chal- lenges of supervised fine-tuning, whose perfor- mance is not robust to distribution shifts. By contrast, the proposed self-consistency prompt- ing approach greatly improves the performance of large language models, enabling GPT-4o to achieve 0.548 SemF1, surpassing the perfor- mance of a fully fine-tuned BART-base model. Finally, we demonstrate the potential of our 025 method to serve as a general NLP infrastruc- ture, exemplified by its application in epidemic event detection from social media.

028 1 Introduction

 Keyphrase prediction is an NLP task that has at- tracted long-lasting research interest [\(Witten et al.,](#page-10-0) [1999;](#page-10-0) [Hulth,](#page-9-0) [2003;](#page-9-0) [Meng et al.,](#page-9-1) [2017\)](#page-9-1). Given doc- uments from various domains such as academic writing, news, social media, or meetings, keyphrase extraction and keyphrase generation models output short phrases aiming at encapsulating the key enti- ties and concepts mentioned by the document. Be- yond a number of information retrieval applications [\(Kim et al.,](#page-9-2) [2013;](#page-9-2) [Tang et al.,](#page-9-3) [2017;](#page-9-3) [Boudin et al.,](#page-8-0) [2020\)](#page-8-0), keyphrase prediction methods are widely incorporated into the pipelines of other NLP tasks such as natural language generation [\(Yao et al.,](#page-10-1)

Figure 1: An illustration of on-demand keyphrase generation. Given diverse user goals, models are required to generate goal-conforming keyphrases or abstain.

[2019;](#page-10-1) [Li et al.,](#page-9-4) [2020\)](#page-9-4), text summarization [\(Dou](#page-8-1) **042** [et al.,](#page-8-1) [2021\)](#page-8-1), and text classification [\(Berend,](#page-8-2) [2011\)](#page-8-2). **043**

Despite their wide application in diverse scenar- **044** ios, which may have diverse requirements on the **045** types of keyphrases, existing keyphrase prediction **046** methods generally follow a suboptimal assumption: **047** for every document, the model shall predict a *sin-* **048** *gle* application-agnostic set of keyphrases, which **049** is then evaluated against a *monolithic* set of ref- **050** erences [\(Wu et al.,](#page-10-2) [2023b\)](#page-10-2). This one-size-fits-all **051** approach fails to cater to both downstream appli- **052** cations' varied requirements of the keyphrase pre- **053** dictions' topic and level of specificity and different **054** expectations from human users with diverse back- **055** grounds. To properly handle such diverse feedback, **056** current approach could only rely on the sample- **057** rerank strategy [\(Zhao et al.,](#page-10-3) [2022;](#page-10-3) [Wu et al.,](#page-10-4) [2023a\)](#page-10-4), **058** which is largely inefficient. Besides, the single- 059 reference setting also biases the intrinsic evaluation, **060** of keyphrase prediction models, as high-frequency **061** topics in keyphrase labels may significantly out- **062** weigh the long-tail keyphrases. 063

To tackle these challenges, we propose *on-* **064** *demand keyphrase generation*, a novel paradigm **065** that predicts keyphrases conditioned on a *goal* phrase that specifies the high-level category or intent of the keyphrase (Figure [1\)](#page-0-0). For existing keyphrase prediction models, this task is challeng- ing as it requires the predictions to be not only cap- turing key information but also goal-conforming. Furthermore, the models are required to accept *open-vocabulary* goals, a significant step beyond predicting keyphrases with predefined categories or ontology [\(Park and Caragea,](#page-9-5) [2023\)](#page-9-5).

 To test on this new task, we meticulously curate and release METAKP, a large-scale on-demand keyphrase generation benchmark covering four datasets, 7500 documents, and 3760 unique goals from the news and the biomedical text domain. We build a scalable labeling pipeline that combines GPT-4 [\(OpenAI,](#page-9-6) [2023\)](#page-9-6) and human annotators to construct high-quality goals from keyphrases (Fig- ure [2\)](#page-2-0). For evaluation, we design two tasks: judg- ing the relevance of goals and generating goal- conforming keyphrases. For the latter, we employ the state-of-the-art evaluation method [\(Wu et al.,](#page-10-2) [2023b\)](#page-10-2) to conduct a semantic-based evaluation.

 Using METAKP, we develop both super- vised and unsupervised methods for on-demand keyphrase generation. For the supervised method, we design a multi-task fine-tuning approach to en- able sequence-to-sequence pre-trained language models to self-determine the relevance of a goal and selectively generate keyphrases (Section [4.1\)](#page-4-0). Then, in Section [4.2,](#page-5-0) we introduce an unsupervised self-consistency prompting approach leveraging the strong ability of large language models (LLMs) to propose goal-related keyphrase candidates and their propensity to predict high quality keyphrases with higher frequencies and ranks. Comprehensive experiments reveal the following insights:

- **103** 1. METAKP represents a challenging benchmark **104** for keyphrase generation. Flan-T5-XL, the **105** strongest fine-tuned model, only achieves an **106** average of 0.609 Satisfaction Rate across all **107** the datasets, and zero-shot prompting GPT-4o, **108** a strong LLM, only achieves 0.492 SR.
- **109** 2. The proposed fine-tuning approach enables **110** jointly learning goal relevance judgment and **111** keyphrase generation without impeding each **112** task's performance (Section [5.3\)](#page-6-0).
- **113** 3. The proposed self-consistency prompting ap-**114** proach greatly improves the performance of **115** LLMs, enabling GPT-4o to achieve 0.548 116 **SemF1**, surpassing the performance of a fully **117** fine-tuned BART-base model.

4. Supervised fine-tuning can fail to general- **118** ize on out-of-distribution testing data. By **119** contrast, LLM-based unsupervised method **120** achieves consistent performance in all the do- **121** mains, especially in the news domain, where **122** GPT-4o outperforms supervised Flan-T5-XL **123** by 19% in out-of-distribution testing. **124**

Finally, we demonstrate the potential of ondemand keyphrase generation as a general NLP **126** infrastructure. Specifically, we use event detec- **127** tion for epidemics prediction [\(Parekh et al.,](#page-9-7) [2024\)](#page-9-7) **128** as a test bed. By constructing simple goals from **129** event ontology and attempting to extract relevant **130** keyphrases from social media text, we show that **131** an on-demand keyphrase generation model has the **132** potential to extract epidemic-related trends similar **133** to an event detection model trained on task-specific **134** data. The benchmark and experimental code will **135** be released to facilitate further research. **136**

2 Related Work **¹³⁷**

Keyphrase Prediction with Types This work **138** is closely related to prior work on modeling **139** keyphrases with pre-defined types or categories. **140** Early datasets are often derived from named en- **141** tity recognition, where keyphrase spans are ex- **142** [t](#page-9-8)racted with entity type tags [\(QasemiZadeh and](#page-9-8) **143** [Schumann,](#page-9-8) [2016;](#page-9-8) [Augenstein et al.,](#page-8-3) [2017;](#page-8-3) [Luan](#page-9-9) **144** [et al.,](#page-9-9) [2018\)](#page-9-9). Notable modeling approaches in- **145** clude using intermediate task for training strong **146** [a](#page-9-10)nd transferable encoder representations [\(Park and](#page-9-10) **147** [Caragea,](#page-9-10) [2020\)](#page-9-10) as well as multi-task fine-tuning **148** [\(Park and Caragea,](#page-9-5) [2023\)](#page-9-5). In addition, existing lit- **149** erature has explored inducing high-level type vari- **150** able for more accurate keyphrase prediction, such **151** as topic-guided keyphrase generation [\(Wang et al.,](#page-10-5) **152** [2019;](#page-10-5) [Zhang et al.,](#page-10-6) [2022a\)](#page-10-6), hierarchical keyphrase **153** generation [\(Wang et al.,](#page-10-7) [2016;](#page-10-7) [Chen et al.,](#page-8-4) [2020;](#page-8-4) **154** [Zhang et al.,](#page-10-8) [2022b\)](#page-10-8), as well as keyphrase comple- **155** tion [\(Zhao et al.,](#page-10-9) [2021\)](#page-10-9). Compare to these prior **156** work, our benchmark features a massive set of **157** open-vocabulary goals with wide domain cover- **158** age. We design novel supervised and unsupervised **159** modeling approaches that consider up-to-date tech- **160** niques such as large language models. **161**

On-Demand Information Extraction Our work **162** resonates with the recent trend of designing flexi- **163** ble formulations for information extraction. For **164** instance, [Zhong et al.](#page-10-10) [\(2021\)](#page-10-10) propose a query- **165** focused formulation for the summarization task, **166** and [Zhang et al.](#page-10-11) [\(2023\)](#page-10-11) further extend the task to **167**

Figure 2: The annotation pipeline for METAKP. Starting from human-annotated keyphrases, GPT-4 is instructed to propose high-level goals and self-refine them. Finally, the goals are validated and filtered by humans.

 include five constraints: Length, Extractiveness, Specificity, Topic, and Speaker. Recently, [Jiao et al.](#page-9-11) [\(2023\)](#page-9-11) introduce on-demand information extrac- tion, where models are required to answer queries by extracting information from the associated text and organize it in a tabular format. By comparison, this work pioneers in defining and benchmarking the goal-following ability of keyphrase prediction models. Our resource and methodology lay the foundation for user-controllable keyphrase systems and flexible concept extraction infrastructures.

¹⁷⁹ 3 METAKP Benchmark

180 In this section, we formulate the on-demand **181** keyphrase generation task and introduce the **182** METAKP evaluation benchmark.

183 3.1 Problem Formulation

 The traditional keyphrase prediction task is defined 185 with a tuple: (document X , reference set Y). Given χ , a model directly generates all keyphrase hy- potheses, with approximating Y as the goal. For on-demand keyphrase generation, we introduce an open-vocabulary goal phrase g which describes a category of keyphrases specified by the user. The target of the model, then, is to generate a set of 192 keyphrases based on (\mathcal{X}, g) to approximate the set 193 of goal-conforming keyphrases $\mathcal{Y}_q \subseteq \mathcal{Y}$.

 Figure [1](#page-0-0) provides an intuitive example of the task. We note that for irrelevant goals, $\mathcal{Y}_q = \phi$, which means that an ideal model should not gener- ate any keyphrases given such goals. In addition, **although** \mathcal{Y}_q **varies according to the goal, the univer-**199 sal set of keyphrases $\mathcal Y$ is assumed to be generally

fixed. In other words, g could viewed as a query **200** that specifies a target subset from \mathcal{V} , which enables 201 a wide range of choices for the modeling design. **202**

3.2 Benchmark Creation Pipeline **203**

To evaluate on-demand keyphrase generation, we **204** curate METAKP, a large-scale multi-domain evalu- **205** ation benchmark. The key challenge is to construct **206** general, meaningful, and diverse goals that reflect **207** high-level keyphrase types in real-world scenarios **208** such as document indexing and search engines. To 209 collect high quality goals, we design a model-in- **210** the-loop annotation pipeline that combines GPT-4 **211** [\(OpenAI,](#page-9-6) [2023\)](#page-9-6) with human annotators to infer **212** goals reversely from keyphrase annotations (Fig- **213** ure [2\)](#page-2-0), with four steps detailed as follows. **214**

Keyphrase Annotation by Human Given the **215** document \mathcal{X} , human annotators specify the set of 216 all the possible keyphrases \mathcal{Y} . For METAKP, we di- 217 rectly leverage the expert-curated keyphrases from **218** the respective keyphrase prediction datasets. **219**

Goal Proposal We instruct GPT-4 to propose a **220** high-level goal for each of the keyphrases, and the **221** same goal could be shared by multiple keyphrases^{[1](#page-2-1)}. Concretely, given X, Y , GPT-4 returns a mapping 223 from goals to keyphrases. We present the prompt **224** for this step in Appendix [A.](#page-11-0) **225**

. **222**

Goal Abstraction After the previous step, a draft **226** goal has been associated with each keyphrase. Al- **227** though the proposed goals are relevant, we observe **228** that they are sometimes overly specific. There- **229**

¹We use gpt-4-0613 via the OpenAI API.

 fore, we instruct GPT-4 to perform a round of *self- refinement*, where it attempts to propose a more abstract version for each of the goals in the previ- ous round, or keep the original goals if they are already high-level enough. The full prompt for this step is presented in Appendix [A.](#page-11-0)

 Human Validation We qualitatively find that the outputs from two GPT-4 annotation iterations are sufficiently abstract and diverse. To further im- prove the quality of the goals and reduce the level of duplication, two of the authors conduct a round of filtering to obtain the final goal annotations. As this step does not entail adding new goals, the an- notators achieve a high inter-annotator agreement (detailed in the next section) following the annota- tion guideline, which we present in Appendix [A.](#page-11-0) Finally, we create an instance for each of the fil-**tered goals, taking the form** $(\mathcal{X}, g_i, \mathcal{Y}_{g_i})$ **.**

248 3.3 Dataset Statistics

 We execute the aforementioned goal construction pipeline on four keyphrase prediction datasets cov- ering two domains: news and biomedical text. For each domain, we create both an in-distribution and an out-of-distribution test set.

- **254** KPTimes [\(Gallina et al.,](#page-8-5) [2019\)](#page-8-5) is a large-scale **255** keyphrase generation dataset in the news do-**256** main. The documents are sourced from from **257** New York Times and the keyphrases are cu-**258** rated by professional editors.
- **259** DUC2001 [\(Wan and Xiao,](#page-10-12) [2008\)](#page-10-12) is a widely **260** used keypharse extraction dataset with news **261** articles collected from TREC-9, paired with **262** human-annotated keyphrases.
- **263** KPBiomed [\(Houbre et al.,](#page-9-12) [2022\)](#page-9-12) is a large-**264** scale dataset containing PubMed abstracts **265** paired with keyphrases annotated by paper **266** authors themselves.
- **267** Pubmed [\(Schutz,](#page-9-13) [2008\)](#page-9-13) is a traditional **268** keyphrase extraction dataset in the biomed-**269** ical domain with documents and keyphrases **270** extracted from the PubMed Central.

 We curate a test set using each of these datasets and construct two domain-specific train/validation sets sampled from the training sets from KPTimes and KPBiomed. Table [1](#page-3-0) and Figure [3](#page-3-1) presents the basic statistics of the final datasets. Besides its domain coverage, one strength of METAKP is

Source	Split					#Doc #Inst #Goal Goal #KP/Goal
	Train	1859	7502	1083	1.43	1.32
KPTimes	Val	100	392	148	1.46	1.37
	Test	984	3836	679	1.41	1.33
DUC2001	Test	308	1642	549	1.50	1.53
	Train	1886	7807	1311	1.75	1.27
KPBiomed	Val	100	404	189	1.75	1.32
	Test	994	4136	865	1.76	1.27
Pubmed	Test	1269	4988	843	1.82	1.33

Table 1: Basic statistics of METAKP. $#Inst = number$ of instances in the form $(\mathcal{X}, g, \mathcal{Y}_q)$. IGoall refers to the average number of words in g . Finally, #KP/Goal corresponds to the average cardinality of \mathcal{Y}_q .

Figure 3: A visualization of the goal distribution for the news domain (top) and the biomedical domain (bottom). METAKP features both high-frequency goals and a diverse long-tail goal distribution.

its *diverse* coverage: together, the dataset covers **277** 3760 unique goals, including diverse topics and **278** subjects. While 40% of the instances correspond **279** to the 10 most popular goals in each domain, a **280** substantial number of goals also fall into the long **281** tail distribution, posing significant new challenge **282** in understanding the goal semantics. **283**

To construct METAKP, the two-staged GPT-4 **284** annotation costed approximately 500 USD, and the **285** human annotators worked for approximately 80 **286** hours in total on final data filtering. We randomly **287** sample 50 documents each from KPTimes and KP- **288** Biomed, on which the annotators reach 0.699 Co- **289** hen's Kappa for inter-annotator agreement. Then, **290** the annotators work on the rest documents sepa- **291** rately. When ambiguous cases are found, a discus- **292** sion is conducted to reach agreement. **293**

Irrelevant Goal Sampling To test the ability of **294** keyphrase generation models to abstain from gen- **295** erating keyphrases given irrelevant goals, for each **296** document, we additionally construct a set of irrel- **297** evant goals. Concretely, we cluster the goals in **298** the labelled data and use each document's existing **299** goals as anchors to sample goals that are likely to **300** be irrelevant to the document and thus it is unlikely **301**

 that a keyphrase corresponding to the sampled goal exists for the document. We present the algorithm in the Appendix [A.3.](#page-11-1) Using the algorithm, a bal- anced training set was created for training super-vised methods for goal relevance judgment.

307 3.4 Evaluation Metric

308 With METAKP, we design two tasks to compre-**309** hensively evaluate a model's ability to perform on-**310** demand keyphrase generation.

 Goal Relevance Assessment This task aims to test whether a model can correctly distinguish irrel- evant goals that cannot yield any keyphrase from the relevant goals. As we will show in Section [6,](#page-7-0) this skill is also crucial to enable a wide application of on-demand keyphrase generation models. Fol- lowing recent literature on abstention [\(Feng et al.,](#page-8-6) [2024\)](#page-8-6), we use Abstain F1 as the evaluation metric, which is defined as the harmonic mean of the preci- sion and the recall of a model refusing to generate keyphrases for irrelevant goals.

322 Goal-Oriented Keyphrase Generation Given 323 document \mathcal{X} , a list of goals $g_1, g_2, ..., g_n$, and ref- \mathcal{S}_{24} erences $\mathcal{Y}_{g_1}, \mathcal{Y}_{g_2}, ..., \mathcal{Y}_{g_n}$, we evaluate a model's 325 predictions $P_1, P_2, ..., P_n$ with two metrics:

- **326** 1. Reference Agreement, which assesses the **327** model's ability to generate keyphrases specifi-328 cally corresponding to the goal q_i . Concretely, 329 we calculate and report $SemF1(Y_{g_i}, P_i)$, fol-**330** lowing [Wu et al.](#page-10-2) [\(2023b\)](#page-10-2).
- **331** 2. Satisfactory Rate (SR), which assesses the **332** frequency of the model generating high-**333** quality keyphrases. Concretely, we calcu-334 **late and report** $SR((\mathcal{Y}g_1, P_1), ..., (\mathcal{Y}g_n, P_n))$ **335** as the percentage of goals that have 336 **Sem** $F1(Y_{g_i}, P_i)$ **greater than a threshold^{[2](#page-4-1)}.**

337 4 Modeling Approach

 In this section, we introduce two modeling ap- proaches for on-demand keyphrase generation: a multi-task learning approach for fine-tuning sequence-to-sequence pre-trained language mod- els, and a self-consistency decoding approach for prompting large language models (LLMs).

344 4.1 Multi-Task Supervised Fine-tuning

345 Previous literature has demonstrated the effec-**346** tiveness of fine-tuning sequence-to-sequence pre-

Figure 4: A visualization of the inference process of the proposed sequence-to-sequence generation approach. Based on the document and the goal prefix, the model self-decides the relevance of the goal and selectively generates the keyphrases for relevant goals only.

trained language models for keyphrase generation **347** [\(Kulkarni et al.,](#page-9-14) [2022;](#page-9-14) [Wu et al.,](#page-10-13) [2022,](#page-10-13) [2023a\)](#page-10-4). **348** However, it is unclear how these sequence predic- **349** tion approaches could be adopted for on-demand **350** keyphrase generation. To bridge this gap, we in- **351** troduce a novel formulation to train a sequence-to- **352** sequence model to autoregressively (1) assess the **353** relevance of goals and (2) jointly consider the docu- **354** ment as well as a desired goal to predict keyphrases. **355**

Concretely, we formulate on-demand keyphrase **356** generation as a hierarchical composition of two **357** token prediction tasks. As shown in Figure [4,](#page-4-2) **358** with the document fed in the encoder, the de- 359 coder first models $P(g_i|\mathcal{X})$, the likelihood of g_i 360 being a high-quality relevant goal proposed by real **361** users. The model verbalizes this probability in **362** $P(\langle n/\mathsf{a}\rangle|\mathcal{X}, g_i)$, a special token for rejecting irrel- 363 evant goals. If the goal is determined as relevant, **364** the model proceeds generating the keyphrases ac- **365** cording to the distribution $P(\mathcal{Y}_{g_i} | \mathcal{X}, g_i)$ it learned. **366**

Inference We use prefix-controlled decoding for 367 inference. g_i , followed by a special end-to-goal 368 token <eog>, is fixed as the decoder's start of gen- **369** eration. Then, we use autoregressive decoding to **370** let the model self-assess the relevance of goal and **371** automatically decide the keyphrases to generate. **372**

Training We design a multi-task learning pro- **373** cedure to directly supervise the model on **374** $P(\langle n/a \rangle | \mathcal{X}, g_i)$ and $P(\mathcal{Y}_{g_i} | \mathcal{X}, g_i)$ with a mixture 375 of relevant and irrelevant goals. As the goals pro- **376** vided by users could be arbitrary, we do not directly **377** supervise the model on $P(g_i|\mathcal{X})$. 378

²We fix $\tau = 0.6$. This decision is based [Wu et al.](#page-10-2) [\(2023b\)](#page-10-2), which suggests that the embedding model for $SemF1$ assigns a similarity score of approximately 0.6 for name variations.

 Remark We note that the proposed approach has several advantages. First, both the goal relevance assessment and the keyphrase prediction process are streamlined in a single sequence prediction pro- cess, removing the need for separate architecture or inference pass. Second, since g_i is not fed to the encoder, our model avoids the goal being diluted by the long input context and enables efficient infer- ence by reusing the encoded input representation for predicting keyphrases with different goals.

389 4.2 Prompting Large Language Models

 Large language models (LLMs) that are tuned to follow human instructions have been shown to adapt well to a massive number of tasks de- fined through human queries [\(Ouyang et al.,](#page-9-15) [2022;](#page-9-15) [OpenAI,](#page-9-6) [2023\)](#page-9-6). They have also been demon- strated to achieve promising keyphrase extraction or keyphrase generation performance, especially with semantic-based evaluation [\(Song et al.,](#page-9-16) [2023;](#page-9-16) [Wu et al.,](#page-10-2) [2023b\)](#page-10-2). As on-demand keyphrase extrac- tion could be easily formulated as an instruction- following task, we investigate the potential of LLMs as an unsupervised approach. We start with a simple instruction for judging a goal's relevance:

 Decide if you should reject the high-level category given the title and abstract of a document. One could use the high-level category to write keyphrases from the document.

407 as well as another instruction for keyphrase genera-**408** tion based on a goal:

409 Generate present and absent keyphrases belonging **410** to the high-level category from the given text.

 Our preliminary experiments show that the first instruction already achieves a strong performance in deciding the goal relevance, even approaching supervised models (Section [5.2\)](#page-5-1). However, when it comes to keyphrase generation, LLMs intriguingly misinterpret the task as named entity extraction: they often generate an almost exhaustive list of goal-related entities. To correct this behavior, we hypothesize that LLMs tend to generate salient en- tities more frequently and at an earlier location of the prediction sequence. Inspired by [Wang et al.](#page-10-14) [\(2023\)](#page-10-14), we thus design a novel self-consistency de- coding process to leverage the rank and frequency information in LLMs' samples to filter out phrases that encode the most important information.

 Concretely, using the same instruction and in-**put, we sample K prediction sequences** $(s_1, ..., s_K)$ from the LLM independently, each of which con-tains a variable number of keyphrases. Then, for

each keyphrase p, we define its saliency score as: **430**

$$
score(p) = \frac{freq(p)}{K} \times \frac{freq(p)}{\sum_{i=1,\ldots,K} rank(s_i,p)},
$$

where $freq(p)$ returns the frequency of p in all the 432 samples and $rank(s_i, p)$ returns the rank of p in **433** s_i (starting from 1) or 0 if $p \notin s_i$. The first term 434 rewards keyphrases that frequently present in the **435** samples, and the second term rewards keyphrases **436** with a higher rank. Together, the score is defined to 437 range 0 from 1 regardless of the number of samples **438** or the number of keyphrases a model generates **439** per sample. Finally, we apply threshold filtering **440** and only retain the high quality keyphrases with **441** $score(p)$ greater than or equal to a threshold τ . 442

5 Experiments **⁴⁴³**

5.1 Experimental Setup **444**

Supervised Fine-tuning Using the proposed ob- **445** jective, we fine-tune four sequence-to-sequence **446** models: BART-base/large [\(Lewis et al.,](#page-9-17) [2020\)](#page-9-17) **447** and Flan-T5-large/XL [\(Longpre et al.,](#page-9-18) [2023\)](#page-9-18), **448** with diverse sizes ranging from 140M to 3B. We 449 train the models for 20 epochs with batch size 64, **450** learning rate 3e-5, the Adam optimizer, and a lin- **451** ear decay with 50 warmup steps. The best model **452** checkpoint is chosen based on the keyphrase gen- **453** eration performance on the validation set. **454**

Prompting We use gpt-3.5-turbo-0125 and **455** the gpt-4o-2024-05-13 models via the OpenAI **456** API. We will denote the models as GPT-3.5-Turbo **457** and GPT-4o. We use separate prompts for goal rel- **458** evance judgment and on-demand keyphrase gen- **459** eration. For the first task, greedy search is used. **460** For the second task, we generate 10 samples with 461 $p = 0.95$ and temperature $= 0.7$. The output length 462 is limited 30 tokens, which can accommodate ap- **463** proximately 10 keyphrases. Finally, for filtering, **464** we use $\tau = 0.3$ for all the datasets. 465

We document the full implementation details in 466 Appendix [B,](#page-12-0) including the prompt for language 467 language models, the post-processing process, as **468** well as the details for hyperparameter tuning.

5.2 Main Results **470**

We present the main results for the two tasks in 471 Figure [5](#page-6-1) and Table [2.](#page-6-2) **472**

Goal Relevance Assessment According to Fig- **473** ure [5,](#page-6-1) we find both supervised fine-tuning and unsu- **474** pervised prompting reaches a high performance for **475**

Figure 5: Goal relevance judgment results of different types of models. Zero-shot prompting LLMs achieves a high performance, despite slightly falling below supervised models. Also, GPT-4o does improve over GPT-3.5-Turbo.

Model	Size	Method	$KPTimes^{\ddagger}$		$DUC2001$ ^{$+$}		KPBiomed		Pubmed [*]		Average

Table 2: Experiment results of supervised and unsupervised methods on-demand keyphrase generation. We use different superscripts to denote results that are reported using the models trained on KPTimes (❖) and KPBiomed (✿). $SR =$ satisfaction rate. $SC =$ self-consistency prompting The best results are boldfaced. [†] statistically significantly better than the second highest result with $p < 0.01$, tested via paired t-test.

 assessing whether a goal, as indicated by over 0.85 Abstain F1 scores across all datasets. As model size scales, the out-of-distribution performance scales more readily, while the in-distribution perfor- mance plateaus at Flan-T5-large. With large lan- guage models, we observe strong performance es- pecially on DUC2001, surpassing the performance of Flan-T5-large trained on KPTimes.

 Keyphrase Generation The main results for keyphrase generation are presented in Table [2.](#page-6-2) For supervised methods, we additionally include a "No Goal" baseline, where the model is fine-tuned to generate all the keyphrases for the same document at once. For both BART-base and BART-large, this baseline achieves a low performance, indi- cating the challenging nature of directly lever- aging a keyphrase generation model for the pro- posed task. By comparison, the proposed goal- directed fine-tuning approach improves the perfor- mance by a large margin, with the best Flan-T5-XL model achieving 0.609 SemF1 and 0.544 satisfac- tion rate. On the other hand, directly zero-shot prompting large language models already achieves more superior performance compared to the supervised models trained without any goal. The **500** proposed self-consistency further improves the per- **501** formance substantially, allowing GPT-4o achieve **502** 0.548 SemF1 and 0.475 satisfaction rate. Notably, **503** results demonstrate that the LLM-based approach **504** has the potential to be more generalizable. On 505 DUC2001, all supervised models trained on KPTi- **506** mes demonstrate a poor performance. By contrast, **507** both GPT-3.5-Turbo and GPT-4o are able to sur- **508** pass the performance of all supervised models. **509**

5.3 Analyses **510**

Which parameter affects LLMs the most? In 511 Figure [6,](#page-7-1) we use use KPTimes' validation set to 512 investigate the sensitivity of the LLM-based ap- **513** proach to three hyperparameters: number of sam- **514** ples (K) , threshold τ , and context length of the 515 input. Although multiple samples are essential to **516** high performance, more samples after two only 517 help marginally. In addition, our method is insensi- **518** tive to the threshold setting - the best performance **519** can be obtained by multiple settings between 0.25 **520** and 0.45. Finally, while GPT-3.5-Turbo exhibits **521** a slight performance drop with longer context, **522** GPT-4o is robust to context length variations. **523**

Figure 6: Sensitivity of the self-consistency prompting approach's performance to number of samples, settings of threshold τ , and the input length on KPTimes. The results on KPBiomed is presented in Figure [12.](#page-13-0)

	Ш		OOD

Goal Relevance Only	0.917		0.916				
Keyphrase Only		0.425		0.407			

Table 3: Ablation study on the multi-task learning setup. $AF1 = Abstain F1$, $SR = Satisfactor Rate$.

 Does multi-task learning harm each individual task's performance? In Table [3,](#page-7-2) we conduct an ablation study with BART-base on the supervised training loss. For each ablated component, we mask out the corresponding tokens when calcu- lating the loss. Overall, combining the two learn- ing objectives do not significantly harm the perfor- mance compared to only learning individual tasks, while incurring much less computational overhead. In fact, on KPTimes, the two tasks are constructive - learning goal relevance helps generating better goal-conforming keyphrases, and vice versa.

⁵³⁶ 6 METAKP in the Wild: Event Detection

537 Finally, we demonstrate the potential of on-demand **538** keyphrase generation as general NLP infrastructure, **539** using event detection (ED) as a case study.

540 We leverage the testing dataset used in SPEED **541** [\(Parekh et al.,](#page-9-7) [2024\)](#page-9-7), which contains time-stamped social media posts related to Monkeypox[3](#page-7-3) **542** . From

Figure 7: Number of events/keyphrases extracted for Monkeypox as a function of time. The true trend and SPEED outputs are solicited from [Parekh et al.](#page-9-7) [\(2024\)](#page-9-7).

the SPEED ontology, we curate seven epidemic- **543** related goals: *disease infection, epidemic spread,* **544** *epidemic prevention, epidemic control, symptom,* **545** *recover from disease, death from epidemic*. Then, **546** we run a FLAN-T5-large model trained on all train- **547** ing data from METAKP to assess the relevance of **548** each goal against each social media post. If the **549** probability of <n/a> following <eog> is greater **550** than 0.001, the goal is judged relevant to the post **551** and thus the underlying event is likely. **552**

As shown in Figure [7,](#page-7-4) we observe that this **553** keyphrase-based paradigm is able to extract trends **554** that are similar to an ED model trained on SPEED **555** [\(Parekh et al.,](#page-9-7) [2024\)](#page-9-7). Intuitively, given a sentence **556** containing "getting vaccination", instead of focus- **557** ing on the trigger "get", on-demand keyphrase **558** generation is able focus more on "vaccination", **559** given the goal "epidemic control". In this way, on- **560** demand keyphrase generation models can both be **561** naturally repurposed for ED and also promises to **562** extract supporting topics related to the the event. **563**

7 Conclusion **⁵⁶⁴**

We introduce on-demand keyphrase generation, **565** targeting the need for dynamic, goal-oriented **566** keyphrase prediction tailored to diverse applica- **567** tions and user demands. A large-scale, multi- **568** domain, human-verified benchmark METAKP was **569** curated and introduced. We designed and evalu- **570** ated both supervised and unsupervised methods **571** on METAKP, highlighting the strengths of self- **572** consistency prompting with large language mod- **573** els. This approach significantly outperformed tra- **574** ditional fine-tuning methods under domain shifts, **575** showcasing its robustness and the broader applica- 576 bility of our methodology. Finally, we underscore **577** the versatility of on-demand keyphrase generation **578** in practical applications such as epidemic event ex- **579** traction, promising a new direction for keyphrase **580** generation as general NLP infrastructure. **581**

³We solicited the dataset and outputs from the authors.

⁵⁸² Limitations

 In this work, we propose the novel on-demand keyphrase generation paradigm. In the future, several exciting directions exist for extending the paradigm as well as the METAKP benchmark:

- **587** 1. Multi-lingual Keyphrase Generation. **588** METAKP only covers data in English. **589** Further benchmarking and enhancing the **590** multilingual and cross-lingual on-demand **591** keyphrase generation ability is an important **592** future direction.
- **593** 2. Wider Domain Coverage. We mainly focus **594** on the news and the biomedical text domain as **595** they have been shown as important application **596** domains for keyphrase generation.
- **597** 3. Flexible Instructions. In this work, the "de-**598** mand" from the users are generally defined **599** as topics or categories of keyphrases. How-**600** ever, future work could expand this definition **601** to include demands that specify stylistic con-**602** straints such as the number of keyphrases, the **603** length, and their formality.

⁶⁰⁴ Ethics Statement

 As a new task and paradigm, on-demand keyphrase generation may bring new security risks and ethi- cal concerns. To begin with, although keyphrase generation models generally have outstanding un- derstanding of phrase saliency, they generally have a shallower understanding of semantics and factu- ality. Thus, when pairing keyphrases with goals, potential misinformation could be created. For instance, when queried with "cure" as a goal, a model may return certain concepts that are factu- ally wrong. In addition, when queries contain cer- tain occupations as goals, a keyphrase generation model may reinforce existing gender stereotypes by selectively generating and ignoring entities with a certain gender. We view these possibilities as potential risks and encourage a thorough redteam- ing process before deploying on-demand keyphrase generation systems in real-world products.

 We use KPTimes and KPBiomed data dis- tributed by the original authors. For DUC2001 and **PubMed, we access the data via ake-datasets^{[4](#page-8-7)}. KP-** Times was released under Apache-2.0 license, and we cannot find licensing information for DUC2001, KPBiomed, and PubMed. ake-datasets was also released under Apache-2.0. No additional preprocessing is performed in METAKP except lower- **630** casing and tokenization. While we mainly rely on **631** the original authors for dataset screening to remove **632** sensitive and harmful information, we also actively **633** monitor the data quality during in the human filter- **634** ing process and remove any document that could **635** cause privacy or ethics concerns. As OpenAI mod- **636** els are involved in the data curation process, our **637** code and datasets will be released with MIT license **638** with a research-only use permission. 639

Supplementary Material: Appendices

888 In this section, we describe the details of the con-**889** struction process of METAKP.

 A.1 GPT-4 Annotation Goal Proposal In Figure [8,](#page-11-2) we show the prompt used to instruct GPT-4 to propose goals from the document and human-annotated keyphrases. We truncate the document body to four sentences as

895 its role is only providing essential contextual. The **896** LLM is instructed to propose all the goals for all the

897 keyphrases together, which helps the model group

898 together keyphrases that share the same goal.

Document Title: {title} First 4 sentences of the document body: {body} Keyphrases (separated by ";"): {keyphrases} For each keyphrase, generate an abstract category for the keyphrase. Examples include process, task, material, tool, measurement, model, technology, and metric etc. Do not limit yourself to the examples. Make sure that the categories are informative in the domain of science and appearing natural as if that assigned by a well-read user. Return a list of dictionaries, each with two keys - "keyphrase" and "category". If two keyphrases have the same category, make sure that they are labelled with the same phrase. Do not change how the keyphrases appear, including their cases. Return json only and do not say anything else.

887 A METAKP Construction Details

Figure 8: Prompt used for instructing GPT-4 to generate the goals from a document and keyphrases.

 Goal Refinement Then, we instruct GPT-4 to refine the goals by trying to generate more abstract versions of them. The prompt is shown in Figure [9.](#page-11-3) As we perform the refinement directly from the chat history of the previous step, we omit the previous prompt and step 1 model outputs.

... step 1 prompt and model outputs ...

Can you make the categories more abstract, yet still informative to the keyphrase? If the categories are already abstract enough, you do not need to change. Return json only.

Figure 9: Prompt used for instructing GPT-4 to improve the abstractiveness of the proposed goals.

905 For both of the steps, we use greedy search and **906** cap the output to 400 tokens. We parse the results **907** string into json format to extract the goals.

A.2 **Human Validation 908**

Next, based on the two rounds of proposed goals, **909** the two authors (student researchers familiar with **910** NLP and the keyphrase generation task) filter **911** out high quality goals as the final benchmarking **912** dataset. We emphasize that this decision is required **913** due to the nature of the task, which requires expert **914** annotators to ensure a high data quality. The con- **915** sent to use and release the annotation traces was **916** obtained from both of the authors. The type of re- **917** search conducted by this work is automatically de- **918** termined exempt from by the authors' institution's **919** ethics review board. We design and enforce two **920** major guidelines during the annotation process: **921**

- 1. Remove a goal if it is semantically equivalent **922** to or a subtype of some another goal that is **923** more abstract. 924
- 2. Remove a goal if it so abstract that it could **925** also enclose other keyphrases not currently **926** paired with the goal. This criterion includes **927** overly vague goals (e.g., "concept") and goals **928** that corresponds to the topic of the entire **929** pssage (e.g., "chemistry concepts"). **930**

As mentioned in Section [3,](#page-2-2) this process allows **931** the annotator reach a high inter-annotator agree- **932** ment of 0.699 Cohen's Kappa. In addition, the **933** annotator actively engage in a discussion whenever **934** ambiguous cases are found. Finally, we conduct a **935** rule-based postprocessing with two stages. **936**

- 1. Goal Removal. We remove the following **937** goals as they represent overly general goals: **938** entity, process, concept. **939**
- 2. Goal Unification. We merge the following **940** goal labels as they represent the same mean- **941** ing. Table [4](#page-12-1) presents the source and target **942** goals. Note that to preserve the diversity of **943** the goals, we refrain from merging aggres- **944** sively and only merge the basic cases that **945** may be result from annotation discrepancy. **946**

A.3 Negative sampling Algorithm **947**

To construct the training and evaluation data for **948** evaluating the model's ability to reject irrelevant **949** goals, we design a simple algorithm to sample ir- **950** relevant goals. Concretely, we pool together all **951** the existing goals from the same dataset as the uni- **952** versal goal set and leverage the phrase embedding **953** model released by [\(Wu et al.,](#page-10-2) [2023b\)](#page-10-2) to embed all **954** the phrases. Then, for each goal from the docu- **955**

Source Goals	Target Goals			
place, geographical location	location			
person, people, individual person	individual			
geopolitical entity	country			
event	event			
profession	occupation			
belief system	religion			
incident outcome	outcome			
subject	topic			
incident	event			
equipment	equipment			
procedure	procedure			

Table 4: Goal merging directions for METAKP label cleaning. We replace all occurrences of source goals with target goals.

956 ment, we use it as an anchor to retrieve d% most 957 dissimilar goals. We use $d = 50$ for all the datasets. From these goals, we sample a goal that is not asso- ciated with the document as the irrelevant goal ac- cording to the frequency distribution of these goals appearing as relevant goals in the final dataset. We additionally design a frequency match constraint, which enforces that the frequency of a goal g ap- pearing as an irrelevant goal should not exceed the frequency it appears as a relevant goal. In practice, the frequency match constraint is applied first. If no eligible goals remain, we sample a goal from the 968 d% most dissimilar goals according to frequency.

969 B Implementation Details

970 B.1 Supervised Fine-tuning

 For multi-task learning with BART and Flan-T5, we base our implementation on the Huggingface Trans- formers implementations provided by [\(Wu et al.,](#page-10-4) [2023a\)](#page-10-4) and train for 20 epochs with early stopping. We use learning rate 3e-5, linear decay, batch size 64, and the AdamW optimizer. Due to the context limitations of Flan-T5, all the input documents for BART and Flan-T5 are truncated to 512 tokens to enable a fair comparison. We perform a careful hyperparameter search over the learning rate, batch size, and warm-up steps. The corresponding search spaces are {1e-5, 3e-5, 6e-5, 1e-4}, {16, 32, 64, 128}, and {50, 100, 250, 500}. The best hyper- parameters are chosen based on the performance on the validation set. To decode from the fine- tuned models, we fix the decoder's prefix using the constrained decoding functionalities provided by Huggingface Transformers and use greedy search

to complete the suffix. 989

The fine-tuning experiments are performed on **990** a local GPU server with eight Nvidia RTX A6000 **991** GPUs (48G each). We use gradient accumula- **992** tion to achieve the desired batch sizes. Fine- **993** tuning BART-base, BART-base, Flan-T5-large, **994** and Flan-T5-XL take, respectively. **995**

B.2 Large Language Models **996**

We present the prompts for prompting large lan- 997 guage models for goal relevance judgment and **998** goal-conforming keyphrase generation in Figure [10](#page-12-2) **999** and Figure [11.](#page-12-3) **1000**

In this task you will need to decide if you should reject the high-level category given the title and abstract of a document. One could use the high-level category to write keyphrases from the document. If you decide the category is relevant to the document, generate yes; if the category is not relevant, generate no. Do not output anything else. Document Title: {title}

Document Abstract: {body} High-level Category: {goal}

Relevant? (yes or no):

Figure 10: Prompt used for goal relevance judgment.

Generate present and absent keyphrases belonging to the high-level category from the given text, separated by commas. Do not output anything else. Document Title: {title} Document Abstract: {body} High-level Category: {goal} Keyphrases (Must be of category "{goal}"):

Figure 11: Prompt used for on-demand keyphrase generation with LLMs.

For all the results reported in the pa- **1001** per, we use gpt-3.5-turbo-0125 and the **1002** gpt-4o-2024-05-13 models via the OpenAI API. **1003**

For goal relevance judgment, we use greedy de- 1004 coding and record the yes/no predictions for evalu- **1005** ation. The document body is truncated to the first **1006** five sentences as we find providing longer context **1007** barely improves the performance. **1008**

For on-demand keyphrase generation, the input 1009 length is truncated to 4000 tokens. We generate 1010 10 samples with $p = 0.95$ and temperature $= 0.7$. 1011 The output length is limited to 30 tokens, which accommodate approximately 10 keyphrases. Finally, **1013**

1014 for filtering, we set a fixed threshold $\tau = 0.3$. We lower-case all the outputs and use a string match- ing algorithm to remove excessive parts generated by the model such as "present keyphrases: ". The method's sensitivity to the hyperparameter settings is presented in Figure [6](#page-7-1) and Figure [12.](#page-13-0)

 Since the proposed LLM-based methods are un- supervised, we refrain from extensively tuning the hyperparameters. The only exception is that we use the validation sets to determine a reasonable good 1024 setting of the sample size K and the threshold τ , which is uniformly applied to all the datasets.

Figure 12: Sensitivity of the self-consistency prompting approach's performance to number of samples, settings of threshold τ , and the input length on KPBiomed.

¹⁰²⁶ C Qualitative Study

 In Figure [13](#page-14-0) and Figure [14,](#page-15-0) we present and com- pare the outputs of Flan-T5-XL, zero-shot sam- pling from GPT-4o, and self-consistency sampling from GPT-4o in two domains. Compared to su- pervised models, which often generates subopti- mal keyphrases under distribution shift, GPT-4o exhibits consistent high recall across domains, and the self-consistency reranking process further fil- ters high quality goals from the zero-shot keyphrase predictions across multiple samples.

Domain: News Source: KPTimes Title: more connecticut schools fall short of "no child left behind" standards Abstract: since [digit], when president bush signed the federal no child left behind law, schools in connecticut have scrambled to revamp curriculums , step up professional development for teachers and continually assess students ' test scores to comply with the law ' s requirements . it is an effort that has dominated the agendas of school officials not just in connecticut , but all over the nation , and not everyone is happy that test results have become such a focus . when results of the latest test scores were announced a few weeks ago , about [digit] percent , or [digit] , of the public schools in connecticut did not make the grade under the federal law , state officials said . the state added [digit] schools to its list of schools that failed to meet the federal benchmarks . _________________ Goal 1: institution Reference: "education and schools" Prediction (**Flan-T5-XL**): "education and schools" Prediction (**GPT-4o (zero-shot**): "connecticut schools", "federal government", "state department of education", "norwalk public schools", "greenwich school district", "greenwich public schools" Prediction (**GPT-4o (self-consistency**): "connecticut schools", "state department of education" Goal 2: law Reference: "no child left behind act" Prediction (**Flan-T5-XL**): "no child left behind act" Prediction (**GPT-4o (zero-shot**): "no child left behind", "federal no child left behind law", "federal law", "federal government", "new accountability system", "adequate yearly progress" Prediction (**GPT-4o (self-consistency**): "no child left behind", "no child left behind law" Source: DUC2001 (out-of-distribution) Title: (empty) Abstract: millions of gallons of crude oil that spilled when a tanker ran aground spread across a wildlife - rich stretch of ocean saturday , and alaska ' s chief environmental officer criticized cleanup efforts as too slow . the biggest oil spill in u . s . history created a slick about seven miles long and seven miles wide in prince william sound . the coast guard said only reef island and the western edge of bligh island had been touched by the slick . Title: contemporary trend of acute kidney injury incidence and incremental costs among us patients undergoing percutaneous coronary procedures .

Abstract: objectives to assess national trends of acute kidney injury (aki) incidence, incremental costs, risk factors, and readmissions among patients undergoing coronary angiography (cag) and / or percutaneous coronary intervention (pci) during [digit] - [digit] . background aki remains a serious complication for patients undergoing cag / pci . evidence is lacking in contemporary aki trends and its impact on hospital resource utilization . methods patients who underwent cag / pci procedures in [digit] hospitals were identified from premier healthcare database . aki was defined by icd - [digit] / [digit] diagnosis codes $\left[\frac{\text{digit}}{\text{weight}}\right]$. Goal 1: medical condition Reference: "acute kidney injury", "chronic kidney disease", "nephropathy" Prediction (**Flan-T5-XL**): "acute kidney injury" Prediction (**GPT-4o (zero-shot**): "acute kidney injury", "chronic kidney disease", "anemia", "diabetes" Prediction (**GPT-4o (self-consistency**): "acute kidney injury", "chronic kidney disease", "anemia" Goal 2: medical procedure Reference: "percutaneous coronary intervention" Prediction (**Flan-T5-XL**): "percutaneous coronary intervention" Prediction (**GPT-4o (zero-shot**): "percutaneous coronary intervention", "coronary angiography", "coronary procedures", "inpatient procedures", "outpatient procedure" Prediction (**GPT-4o (self-consistency**): "percutaneous coronary intervention", "coronary angiography" Source: PubMed (out-of-distribution) Title: surviving sepsis campaign : international guidelines for management of severe sepsis and septic shock : [digit] Abstract: objective to provide an update to the original surviving sepsis campaign clinical management guidelines, 201c surviving sepsis campaign guidelines for management of severe sepsis and septic shock , 201d published in [digit] . introduction severe sepsis (acute organ dysfunction secondary to infection) and septic shock (severe sepsis plus hypotension not reversed with fluid resuscitation) are major healthcare problems, affecting millions of individuals around the world each year, killing one in four (and often more), and increasing in incidence [[digit] 2013 [digit]]. similar to polytrauma , acute myocardial ˘ infarction , or stroke , the speed and appropriateness of therapy administered in the initial hours after severe sepsis develops are likely to influence outcome . Goal 1: medical condition Reference: "sepsis", "severe sepsis", "septic shock", "sepsis syndrome", "infection" Prediction (**Flan-T5-XL**): "sepsis" Prediction (**GPT-4o (zero-shot**): "acute kidney injury", "chronic kidney disease", "anemia", "diabetes" Prediction (**GPT-4o (self-consistency**): "severe sepsis", "septic shock" Goal 2: healthcare initiative Reference: "surviving sepsis campaign" Prediction (**Flan-T5-XL**): "surviving sepsis campaign" Prediction (**GPT-4o (zero-shot**): "surviving sepsis campaign", "international guidelines", "management of severe sepsis", "septic shock", "clinical management guidelines", "evidence-based methodology" Prediction (**GPT-4o (self-consistency**): "surviving sepsis campaign"

Title: keratinocyte serum - free medium maintains long - term liver gene expression and function in cultured rat hepatocytes by preventing the loss of liver - enriched transcription factors

Abstract: freshly isolated hepatocytes rapidly lose their differentiated properties when placed in culture . therefore , production of a simple culture system for maintaining the phenotype of hepatocytes in culture would greatly facilitate their study . our aim was to identify conditions that could maintain the differentiated properties of hepatocytes for up to [digit] days of culture . adult rat hepatocytes were isolated and attached in williams 2019 medium e containing [digit] % serum . the medium was changed to either fresh williams 2019 medium e or keratinocyte serum - free medium supplemented with dexamethasone, epidermal growth factor and pituitary gland extract .
 $\frac{1}{2}$ = $\frac{1}{2}$ =

Goal 1: biological extract

Reference: "pituitary gland extract"

Prediction ($\mathsf{Flan\text{-}T5\text{-}XL}$): "pituitary gland extract"

Prediction (**GPT-4o (zero-shot**): "keratinocyte serum-free medium", "Williams2019 medium E", "dexamethasone", ˘ "epidermal growth factor", "pituitary gland extract"

Prediction (**GPT-4o (self-consistency**): "keratinocyte serum-free medium", "keratinocyte serum"

Goal 2: molecular biology technique

Reference: "reverse transcription polymerase chain reaction"

Prediction (**Flan-T5-XL**): "cell culture"

Prediction (**GPT-4o (zero-shot**): "immunohistochemistry", "western blotting", "rt-pcr", "immunofluorescence staining", "collagenase perfusion technique"

Prediction (**GPT-4o (self-consistency**): "western blotting", "rt-pcr", "immunohistochemistry"
