

# GENERALIZING WEISFEILER-LEHMAN KERNELS TO SUBGRAPHS

**Anonymous authors**

Paper under double-blind review

## ABSTRACT

Subgraph representation learning has been effective in solving various real-world problems. However, current graph neural networks (GNNs) produce suboptimal results for subgraph-level tasks due to their inability to capture complex interactions within and between subgraphs. To provide a more expressive and efficient alternative, we propose WLKS, a Weisfeiler-Lehman (WL) kernel generalized for subgraphs by applying the WL algorithm on induced  $k$ -hop neighborhoods. We combine kernels across different  $k$ -hop levels to capture richer structural information that is not fully encoded in existing models. Our approach can balance expressiveness and efficiency by eliminating the need for neighborhood sampling. In experiments on eight real-world and synthetic benchmarks, WLKS significantly outperforms leading approaches on five datasets while reducing training time, ranging from 0.01x to 0.53x compared to the state-of-the-art.

## 1 INTRODUCTION

Subgraph representation learning has effectively tackled various real-world problems (Bordes et al., 2014; Luo, 2022; Hamidi Rad et al., 2022; Maheshwari et al., 2024). However, existing graph neural networks (GNNs) still produce suboptimal representations for subgraph-level tasks since they fail to capture arbitrary interactions between and within subgraph structures. These GNNs cannot capture high-order interactions beyond and even in their receptive fields. Thus, state-of-the-art models for subgraphs have to employ hand-crafted channels (Alsentzer et al., 2020), node labeling (Wang & Zhang, 2022), and structure approximations (Kim & Oh, 2024) to encode subgraphs’ complex internal and border structures.

As an elegant and efficient alternative, we generalize graph kernels to subgraphs, which measure the structural similarity between pairs of graphs. We propose WLKS, the Weisfeiler-Lehman (WL) Kernel for Subgraphs based on WL graph kernel (Shervashidze & Borgwardt, 2009). Specifically, we apply the WL algorithm (Leman & Weisfeiler, 1968) on induced  $k$ -hop subgraphs around the target subgraph for all possible  $k$ s. The WL algorithm’s output (i.e., the color histogram) for each  $k$  encodes structures in the receptive field of the  $k$ -layer GNNs; thus, the corresponding kernel matrix can represent the similarity of  $k$ -hop subgraph pairs. A classifier using this kernel can be trained without GPUs in a computationally efficient way compared to deep GNNs.

To enhance the expressive power, we linearly combine kernel matrices of different  $k$ -hops. The motivation is that simply using larger hops for WL histograms does not necessarily lead to more expressive representations. We theoretically demonstrate that WL histograms of the  $(k + 1)$ -hop are not strictly more expressive than those of  $k$ -hop in distinguishing isomorphic structures, while  $(k + 1)$ -hop structures include entire  $k$ -hop structures. Therefore, combining kernel matrices across multiple  $k$ -hop levels can capture richer structural information around subgraphs.

However, sampling  $k$ -hop subgraphs can increase the time and space complexity, as the number of nodes in the  $k$ -hop neighborhoods grows exponentially (Hamilton et al., 2017). To mitigate this issue, we choose only two values of  $k$ : 0 and the diameter  $D$  of the global graph. No neighborhood sampling is required for the case where  $k = 0$  since it only uses the internal structure. When  $k$  is set to the diameter  $D$ , the expanded subgraph encompasses the entire global graph, making the  $k$ -hop neighborhood identical for all subgraphs. Consequently, there is no need for explicit neighborhood sampling in this case; we only perform the WL algorithm on the global graph once. This approach balances expressiveness and efficiency, providing a practical solution for subgraph-level tasks.

We evaluate WLKS’s classification performance and efficiency with four real-world and four synthetic benchmarks (Alsentzer et al., 2020). Our model outperforms the best-performed methods across five of the eight datasets. Remarkably, this performance is achieved with  $\times 0.01$  to  $\times 0.53$  training time compared to the state-of-the-art models. Moreover, unlike existing models, WLKS does not require pre-computation, pre-training embeddings, utilizing GPUs, and searching a large hyperparameter space.

The main contributions of our paper are summarized as follows. First, we propose WLKS, a generalization of graph kernels to subgraphs. Second, we theoretically show that combining WLKS matrices from multiple  $k$ -hop neighborhoods can increase the expressiveness. Third, we evaluate our method on real-world and synthetic benchmarks and demonstrate superior performance in a significantly efficient way. We make our code available for future research<sup>1</sup>.

## 2 RELATED WORK

WLKS is a ‘graph kernel’ method designed for ‘subgraph representation learning.’ This section explains both of these areas and their relationship to our model.

**Subgraph Representation Learning** Subgraph representation learning can address various real-world challenges by capturing higher-order interactions that nodes, edges, or entire graphs cannot model. For example, subgraphs can formulate diseases and patients in gene networks (Luo, 2022), teams in collaboration networks (Hamidi Rad et al., 2022), and communities in mobile game user networks (Zhang et al., 2023). Existing methods are often domain-specific (Zhang et al., 2023; Li et al., 2023; Trümper et al., 2023; Ouyang et al., 2024; Maheshwari et al., 2024) or rely on strong assumptions about the subgraph (Meng et al., 2018; Hamidi Rad et al., 2022; Kim et al., 2022; Luo, 2022; Liu et al., 2023), limiting their generalizability.

Recently, deep graph neural networks, which are universal for subgraphs, have been proposed, but they often generate suboptimal representations due to their inability to capture arbitrary interactions between and within subgraph structures. They struggle to account for high-order interactions beyond their limited receptive fields; thus, they should incorporate additional techniques including hand-crafted channels (Alsentzer et al., 2020), node labeling (Wang & Zhang, 2022), random-walk sampling (Jacob et al., 2023), and structural approximations (Kim & Oh, 2024). In contrast, we design kernels that can capture local and global interactions of subgraphs, respectively, to enable simple but strong subgraph prediction.

**Graph Kernels** Graph kernels are algorithms to measure the similarity between graphs to enable the kernel methods, such as Support Vector Machines (SVMs) to graph-structured data (Vishwanathan et al., 2010). Early examples measure the graph similarity based on random walks (Kashima et al., 2003) or shorted paths (Borgwardt & Kriegel, 2005). One of the most influential graph kernels is the Weisfeiler-Lehman (WL) kernel (Shervashidze & Borgwardt, 2009), which leverages the WL algorithm to refine node labels iteratively, improving the expressiveness of the graph structure comparison. Kernels for graph-level prediction by counting, matching, and embedding subgraphs have been deeply explored (Shervashidze et al., 2009; Kriege & Mutzel, 2012; Yanardag & Vishwanathan, 2015; Narayanan et al., 2016). However, there has been no research on kernels to solve subgraph-level tasks by computing the similarity of subgraphs and their surroundings. To the best of our knowledge, our paper is the first to investigate this approach.

## 3 WL GRAPH KERNELS FOR SUBGRAPH-LEVEL TASKS

This section introduces WLKS, the WL graph kernels generalized for subgraphs. We first describe the original WL algorithm and its extension for subgraphs, which is a foundation of WLKS. Then, we suggest WLKS and its enhancement of expressiveness and efficiency.

### 3.1 SUBGRAPH REPRESENTATION LEARNING

We first formalize subgraph representation learning as a classification task. Let  $\mathcal{G} = (\mathbb{V}, \mathbb{A})$  represent a global graph, where  $\mathbb{V}$  denotes a set of nodes (with  $|\mathbb{V}| = N$ ) and  $\mathbb{A} \subset \mathbb{V} \times \mathbb{V}$  represents a set of edges (with  $|\mathbb{A}| = E$ ). A subgraph  $\mathcal{S} = (\mathbb{V}^{\text{sub}}, \mathbb{A}^{\text{sub}})$  is a graph formed by subsets of nodes and edges in the global graph  $\mathcal{G}$  (with  $|\mathbb{V}^{\text{sub}}| = N^{\text{sub}}$  and  $|\mathbb{A}^{\text{sub}}| = E^{\text{sub}}$ ). There exists a set of  $M$  subgraphs, with  $M < N$ , denoted as  $\mathbb{S} = \{\mathcal{S}_1, \mathcal{S}_2, \dots, \mathcal{S}_M\}$ . In a subgraph classification task, the model learns representation  $\mathbf{h}_i \in \mathbb{R}^F$  and the logit vector  $\mathbf{y}_i \in \mathbb{R}^C$  for  $\mathcal{S}_i$  where  $F$  and  $C$  are the dimension size and the number of classes, respectively.

### 3.2 1-WL ALGORITHM FOR $k$ -HOP SUBGRAPHS

**1-WL for Graphs** We briefly introduce the 1-dimensional Weisfeiler-Lehman (1-WL) algorithm. As illustrated in Algorithm 1, the 1-WL is an iterative node-color refinement by updating node colors based on a multiset of neighboring node colors. This process produces a histogram of refined coloring that captures graph structure, which can distinguish non-isomorphic graphs in the WL isomorphism test.

---

#### Algorithm 1: 1-WL Algorithm

---

**Input:** Graph  $\mathcal{G} = (\mathbb{V}, \mathbb{A})$  and  $T$  iterations

**Output:** Refined node coloring  $(c_1^T, c_2^T, \dots, c_{|\mathbb{V}|}^T)$  for nodes in  $\mathbb{V}$  after  $T$  iterations

---

Initialize  $c_v^0$  for all  $v \in \mathbb{V}$

**for**  $i \leftarrow 1$  **to**  $T$  **do**

**for** *node*  $v \in \mathbb{V}$  **do**

$\mathbb{M}_v \leftarrow$  multiset of labels  $\{c_u^{i-1} \mid u \in \mathcal{N}(v)\}$

$\tilde{c}_v^i \leftarrow$  concatenate  $c_v^{i-1}$  and sorted  $\mathbb{M}_v$

**end**

    Use a bijective function to map each unique  $\tilde{c}_v^i$  to a new color  $c_v^i$

**end**

**return**  $(c_1^T, c_2^T, \dots, c_{|\mathbb{V}|}^T)$

---

**1-WL for Subgraphs (WLS)** We then propose the WLS, the 1-WL algorithm generalized for subgraphs. Since surrounding structures are the core difference between graphs and subgraphs, the main contribution of the WLS lies in encoding the  $k$ -hop neighborhoods of the subgraph. Here,  $k$  will be denoted in superscript as  $\text{WLS}^k$  if a specific  $k$  is given.

Formally, for a subgraph  $\mathcal{S} = (\mathbb{V}^{\text{sub}}, \mathbb{A}^{\text{sub}})$  in a global graph  $\mathcal{G} = (\mathbb{V}, \mathbb{A})$ , the  $\text{WLS}^k$ 's goal is to get the refined colors of nodes in  $\mathbb{V}^{\text{sub}}$ , where each color represents a unique subtree in  $k$ -hop neighborhoods. As in the Algorithm 2, we first extract the  $k$ -hop subgraph  $\mathcal{S}^k$  of  $\mathcal{S}$ , which contains all nodes in  $\mathcal{S}$  as well as any nodes in  $\mathcal{G}$  that are reachable from the nodes in  $\mathcal{S}$  within  $k$  hops. The 1-WL algorithm is then run on this induced  $k$ -hop subgraph to generate the colors of the nodes in  $\mathcal{S}^k$ . The WLS returns the node coloring belonging to the original  $\mathcal{S}$ , not in  $\mathcal{S}^k$ . In general,  $k$ -hop neighborhoods are much larger than the original subgraph, so using all the colors in  $\mathcal{S}^k$  will likely produce a coloring irreverent to the target subgraph.

---

#### Algorithm 2: $\text{WLS}^k$ Algorithm: 1-WL for subgraphs with their $k$ -hop neighborhoods

---

**Input:** A subgraph  $\mathcal{S} = (\mathbb{V}^{\text{sub}}, \mathbb{A}^{\text{sub}})$ , a global graph  $\mathcal{G} = (\mathbb{V}, \mathbb{A})$ , and  $T$  iterations

**Output:** Refined node coloring  $(c_1^T, c_2^T, \dots, c_{|\mathbb{V}^{\text{sub}}|}^T)$  for nodes in  $\mathbb{V}^{\text{sub}}$  after  $T$  iterations

---

Sample  $\mathcal{S}^k = (\mathbb{V}^{\text{sub},k}, \mathbb{A}^{\text{sub},k})$ , which is the induced  $k$ -hop subgraph of  $\mathcal{G}$  around all nodes in  $\mathcal{S}$  reachable within  $k$  hops

Run 1-WL (Algorithm 1) on  $(\mathcal{S}^k, T)$  to get node colors in  $\mathbb{V}^{\text{sub},k}$

**return**  $(c_1^T, c_2^T, \dots, c_{|\mathbb{V}^{\text{sub}}|}^T)$ . Note that this coloring is about nodes in  $\mathcal{S}$ , not  $\mathcal{S}^k$ .

---

Figure 1: An example of  $WLS^k$  algorithm (Algorithm 2) for  $k \in \{0, 1, 2\}$ . **Left:** A subgraph (red shade) and its  $k$ -hop neighborhoods (dashed lines). **Right:** The outputs of  $WLS^k$  algorithm as colors and histograms for the left subgraph. The WLKS kernel matrix for each  $k$  is constructed by an inner product of histogram pairs.

After  $WLS^k$ 's color refinement, we can get a feature vector (or a color histogram)  $\phi_S^k \in \mathbb{R}^{\# \text{colors}}$  which is the aggregation of the refined colors in  $\mathcal{S}$ . Each element  $\phi_S^k[c]$  is the number of occurrences of the color  $c$  in the output of  $WLS^k$ . We illustrate an example of a subgraph and its  $WLS^k$  outputs for different  $k$ s in Figure 1.

**WL Kernels for Subgraphs (WLKS)** Now, we suggest WLKS, the corresponding kernel matrix  $K_{WLS}^k \in \mathbb{R}^{M \times M}$  of which is defined as the number of common subtree patterns of two subgraphs in their  $k$ -hop neighborhoods. That is, each element can be formulated as an inner product of a pair of  $\phi_S^k$ . This WLKS is a valid kernel since  $K_{WLS}^k$  is positive semi-definite for all non-negative  $k$ s, as demonstrated in Proposition 3.1.

**Proposition 3.1.**  $\forall k \geq 0, K_{WLS}^k$  is positive semi-definite (p.s.d.).

*Proof.* Each element in  $K_{WLS}^k$  is defined as an inner product of two feature vectors  $\phi_S^k$ . This leads  $\sum_{i=1}^M \sum_{j=1}^M c_i c_j \langle \phi_i^k, \phi_j^k \rangle = \langle \sum_{i=1}^M c_i \phi_i^k, \sum_{j=1}^M c_j \phi_j^k \rangle = \|\sum_{i=1}^M c_i \phi_i^k\|^2 \geq 0$  for any real  $c$ . Thus,  $K_{WLS}^k$  is positive semi-definite.  $\square$

### 3.3 EXPRESSIVENESS DIFFERENCE OF THE WLS BETWEEN $k$ AND $k + 1$

How do we choose  $k$ ? Intuitively, selecting one large  $k$  seems reasonable since the  $k$ -hop neighborhoods include the  $k'$ -hop structures of all smaller  $k'$ s. Against this intuition, we present a theoretical analysis that the  $WLS^{k+1}$  histogram is not strictly more expressive than the  $WLS^k$  histogram.

In Proposition 3.2, we show that non-equivalent colorings of two subgraphs in  $WLS^{k+1}$  do not guarantee non-equivalent colorings in  $WLS^k$ . This is also true for the inverse: equivalent colorings in  $WLS^{k+1}$  do not guarantee equivalent colorings in  $WLS^k$ .

**Proposition 3.2.** Given two subgraphs  $\mathcal{S}_1$  and  $\mathcal{S}_2$  of a global graph  $\mathcal{G}$  and  $T$  iterations,

$$WLS^{k+1}(\mathcal{S}_1) \not\equiv WLS^{k+1}(\mathcal{S}_2) \not\Rightarrow WLS^k(\mathcal{S}_1) \not\equiv WLS^k(\mathcal{S}_2), \quad (1)$$

$$WLS^{k+1}(\mathcal{S}_1) \equiv WLS^{k+1}(\mathcal{S}_2) \not\Rightarrow WLS^k(\mathcal{S}_1) \equiv WLS^k(\mathcal{S}_2), \quad (2)$$

for any  $k < T$  where  $WLS^k(\mathcal{S}) := WLS^k(\mathcal{S}, \mathcal{G}, T)$  and ' $\equiv$ ' denotes the equivalence of colorings.

*Proof.* We will prove both statements by contradiction.

**Proof of Equation 1** For the sake of contradiction, assume that whenever  $WLS^{k+1}(\mathcal{S}_1) \not\equiv WLS^{k+1}(\mathcal{S}_2)$ , it must follow that  $WLS^k(\mathcal{S}_1) \not\equiv WLS^k(\mathcal{S}_2)$ . Consider two subgraphs  $\mathcal{S}_a$  and  $\mathcal{S}_b$  of a global graph  $\mathcal{G}$  such that their  $k$ -hop neighborhoods are isomorphic, i.e.,  $\mathcal{S}_a^k \equiv \mathcal{S}_b^k$ , but their  $(k+1)$ -hop neighborhoods are not isomorphic. This means that within the  $k$ -hop radius,  $\mathcal{S}_a$  and  $\mathcal{S}_b$  have identical structures, but beyond that, their structures differ. Since  $\mathcal{S}_a^k \equiv \mathcal{S}_b^k$ , applying  $WLS^k$  will yield identical colorings,  $WLS^k(\mathcal{S}_a) \equiv WLS^k(\mathcal{S}_b)$ . However, because their  $(k+1)$ -hop neighborhoods differ, the subtree patterns of height- $T$  rooted captured by  $WLS^{k+1}$  will differ, leading to different colorings,  $WLS^{k+1}(\mathcal{S}_a) \not\equiv WLS^{k+1}(\mathcal{S}_b)$  (e.g., the top part in Figure 2). This contradicts our assumption that  $WLS^{k+1}(\mathcal{S}_1) \not\equiv WLS^{k+1}(\mathcal{S}_2)$  implies  $WLS^k(\mathcal{S}_1) \not\equiv WLS^k(\mathcal{S}_2)$ .

Figure 2: Example pairs of subgraphs that  $\text{WLS}^k$  produces equivalent colorings while  $\text{WLS}^{k+1}$  does not, and vice versa (where  $k = 0$ ). The gray area represents the subgraph.

**Proof of Equation 2** For the sake of contradiction, assume that whenever  $\text{WLS}^{k+1}(\mathcal{S}_1) \equiv \text{WLS}^{k+1}(\mathcal{S}_2)$ , it must follow that  $\text{WLS}^k(\mathcal{S}_1) \equiv \text{WLS}^k(\mathcal{S}_2)$ . Let  $\mathcal{G}$  be a global graph, and consider its two subgraphs  $\mathcal{S}_a$  and  $\mathcal{S}_b$ . Suppose that in  $\mathcal{G}$ ,  $(k+1)$ -hop neighborhoods of  $\mathcal{S}_a$  and  $\mathcal{S}_b$  are identical,  $\text{WLS}^{k+1}(\mathcal{S}_a) \equiv \text{WLS}^{k+1}(\mathcal{S}_b)$ . However, within the  $k$ -hop neighborhoods, the local structures can differ such that the rooted subtree patterns of  $\mathcal{S}_a$  and  $\mathcal{S}_b$  up to height  $T > k$  are not identical,  $\text{WLS}^{k+1}(\mathcal{S}_a) \equiv \text{WLS}^{k+1}(\mathcal{S}_b)$  (e.g., the bottom part in Figure 2). This contradicts our assumption that  $\text{WLS}^{k+1}(\mathcal{S}_1) \equiv \text{WLS}^{k+1}(\mathcal{S}_2)$  implies  $\text{WLS}^k(\mathcal{S}_1) \equiv \text{WLS}^k(\mathcal{S}_2)$ .  $\square$

Our analysis implies that  $\text{WLS}^k$  cannot represent all information on a smaller  $k'$ -hop structure ( $k' < k$ ) from the perspective of graph isomorphism. Then, we need to combine  $\text{WLS}^k$  with multiple  $k$ s to encode various levels of structures. Based on our findings, we suggest  $\text{WLKS-}\mathbb{K}$ , a mixture of  $\text{WLKS}$  for multiple hops  $k \in \mathbb{K}$  where its kernel matrix  $\mathbf{K}_{\text{WLS-}\mathbb{K}}$  is a linear combination of  $\mathbf{K}_{\text{WLS}}^k$ .

$$\mathbf{K}_{\text{WLS-}\mathbb{K}} = \sum_{k \in \mathbb{K}} \alpha_k \mathbf{K}_{\text{WLS}}^k \text{ where } \alpha_k \in \mathbb{R}^+. \quad (3)$$

Note that  $\text{WLKS-}\mathbb{K}$  can be defined even when only one  $k$  is used (e.g.,  $\mathbf{K}_{\text{WLS-}\{0\}} = \alpha_0 \mathbf{K}_{\text{WLS}}^0$  for  $\text{WLKS-}\{0\}$ ).  $\text{WLKS-}\mathbb{K}$  is a valid kernel since a positive linear combination of p.s.d. kernels is p.s.d. (Shervashidze et al., 2011).

### 3.4 SELECTING $k$ FOR MINIMAL COMPLEXITY

In  $\text{WLKS}$ , selecting appropriate values of  $k$  during the  $k$ -hop subgraph sampling is crucial for balancing expressive power and complexity. As the number of nodes in the  $k$ -hop neighborhood grows exponentially with increasing  $k$  (Hamilton et al., 2017), an unbounded increase in  $k$  can result in substantial computation and memory overhead. To mitigate this, we strategically limit the choice of  $k$  to two specific values:  $k = 0$  and  $k = D$ , where  $D$  is the diameter of the global graph  $\mathcal{G}$ .

When  $k = 0$ , the  $\text{WLKS}$  consumes the least computation and memory by using only the internal structure of the subgraph without neighborhood sampling. In contrast, when  $k$  is set to diameter  $D$ , every subgraph has the same  $k$ -hop neighborhood, which is the global graph  $\mathcal{G}$ ; thus, the  $\text{WLS}$  is performed just once on  $\mathcal{G}$  without per-subgraph computations. By using 0 and  $D$ ,  $\text{WLKS-}\{0, D\}$  can capture both the local and the largest global structure of subgraphs. This approach offers a practical model that balances expressive power and efficiency, avoiding excessive computation and memory consumption from intermediate  $k$  values.

### 3.5 COMPUTATIONAL COMPLEXITY

The original  $\text{WL}$  Kernel has a computational complexity of  $\mathcal{O}(T \sum_i E_i^{\text{sub}} + MT \sum_i N_i^{\text{sub}})$  for  $M$  subgraphs,  $T$  iterations, and the number of nodes  $N_i^{\text{sub}}$  and edges  $E_i^{\text{sub}}$  of the subgraph  $i$  (Shervashidze & Borgwardt, 2009). When  $k$  is 0, a set of subgraphs is identical to a set of individual graphs, so its complexity is the same as the original's. When  $k$  is  $D$ , after performing the  $\text{WL}$  algorithm on the global graph once (i.e.,  $\mathcal{O}(TE)$ ), the coloring of each subgraph is aggregated to a histogram (i.e.,  $\mathcal{O}(\sum_i N_i^{\text{sub}})$ ). Thus, the computational complexity of  $\text{WLKS-}\{0, D\}$  is  $\mathcal{O}(T(E + \sum_i E_i^{\text{sub}}) + MT \sum_i N_i^{\text{sub}})$ .

We note that  $\text{WLKS-}\{0, D\}$  do not perform  $k$ -hop neighborhood sampling, which adds a complexity of  $\mathcal{O}(N^{\text{sub},k} + E^{\text{sub},k})$  per subgraph from a breadth-first search from  $\mathbb{V}^{\text{sub}}$ . Learning SVM with pre-

computed kernels has a complexity of  $\mathcal{O}(M^2)$  dependent on the number of subgraphs  $M$ , but this step is typically secondary to the WLS in practice.

### 3.6 GNNs WITH THE WLKS KERNEL MATRIX AS ADJACENCY MATRIX

A kernel expresses the similarity between each data point. In this perspective, we consider the kernel matrix  $\mathbf{K}_{\text{WLS}}$  of WLKS as the adjacency matrix of a weighted graph where subgraphs  $\mathcal{S}$  are nodes. That is, the edge weight between subgraphs  $i$  and  $j$  will be  $\mathbf{K}_{\text{WLS}}[i, j]$ . If deep GNNs are applied to this graph, we can leverage both the expressiveness of WLKS for structures and that of GNNs for features. In this paper, we adopt the state-of-the-art GNN-based models, S2N+0 and S2N+A (Kim & Oh, 2024), for the graph created by WLKS- $\{0, D\}$  as an instantiation of this approach.

Given the original feature  $\mathbf{X} \in \mathbb{R}^{N \times \# \text{ features}}$ , in S2N+0, the hidden feature  $\mathbf{H} \in \mathbb{R}^{M \times \# \text{ features}}$  is a sum of original features in the subgraph, and then a GNN on  $\mathbf{K}_{\text{WLS}} \in \mathbb{R}^{M \times M}$  is applied to get the logit matrix  $\mathbf{Y} \in \mathbb{R}^{M \times \# \text{ classes}}$  for the prediction. S2N+A first encodes each subgraph as an individual graph with a GNN, readout its output to get the hidden feature  $\mathbf{H}$ , then the other GNN on  $\mathbf{K}_{\text{WLS}}$  is applied for the prediction. Formally,

$$\text{WLKS for S2N+0: } \mathbf{H}[i, :] = \mathbf{1}_{N_{\text{sub}}}^{\top} \mathbf{X}[\mathbb{V}_i^{\text{sub}}, :], \mathbf{Y} = \text{GNN}(\mathbf{H}, \mathbf{K}_{\text{WLS}}), \quad (4)$$

$$\text{WLKS for S2N+A: } \mathbf{H}[i, :] = \mathbf{1}_{N_{\text{sub}}}^{\top} \text{GNN}_1(\mathbf{X}[\mathbb{V}_i^{\text{sub}}, :], \mathbf{A}_i^{\text{sub}}), \mathbf{Y} = \text{GNN}_2(\mathbf{H}, \mathbf{K}_{\text{WLS}}), \quad (5)$$

where  $\mathbf{1}_n \in \mathbb{R}^{n \times 1}$  is a vector of ones. Since the kernel matrix is dense for GPUs, we sparsify and normalize it using the same method in the S2N’s paper.

## 4 EXPERIMENTS

This section outlines the experimental setup, covering the datasets, training details, and baselines.

**Datasets** We employ four real-world datasets (PPI-BP, HPO-Neuro, HPO-Metab, and EM-User) and four synthetic datasets (Density, Cut-Ratio, Coreness, and Component) introduced by Alsentzer et al. (2020). Given the global graph  $\mathcal{G}$  and subgraphs  $\mathcal{S}$ , the goal of the real-world benchmark is subgraph classification on various domains: protein-protein interactions (PPI-BP), medical knowledge graphs (HPO-Neuro and HPO-Metab), and social networks (EM-User). For synthetic benchmarks, the goal is to determine the structural properties (density, cut ratio, the average core number, and the number of components) formulated as a classification. Note that WLKS does not need pretrained embeddings. We summarize dataset statistics in Table 1.

**Models** We experiment with five WLKS- $\mathbb{K}$  where  $\mathbb{K}$  is  $\{0\}, \{1\}, \{2\}, \{D\}, \{0, D\}$ . Coefficients  $\alpha$  is set to 1 when one  $k$  is selected, and  $\alpha_0 + \alpha_D = 1$  for WLKS- $\{0, D\}$ . We do a grid search of five hyperparameters: the number of iterations ( $\{1, 2, 3, 4, 5\}$ ), whether to combine kernels of all iterations, whether to normalize histograms, L2 regularization ( $\{2^3/100, 2^4/100, \dots, 2^{14}/100\}$ ), and the coefficient  $\alpha_0$  ( $\{0.999, 0.99, 0.9, 0.5, 0.1, 0.01, 0.001\}$ ). For fusing WLKS- $\{0, D\}$  to S2N, we follow the GCNII-based (Chen et al., 2020) architecture and settings presented in Kim & Oh (2024).

Table 2: Mean performance in micro F1-score on real-world and synthetic datasets over 10 runs. A subscript indicates the standard deviation. The higher the performance, the darker the blue color. The results of baselines are reprinted from respective papers.

**Baselines** We use state-of-the-art GNN-based models for subgraph classification tasks as baselines: Subgraph Neural Network (SubGNN; Alsentzer et al., 2020), GNN with Labeling trickS for Subgraph (GLASS; Wang & Zhang, 2022), Variational Subgraph Autoencoder (VSubGAE; Liu et al., 2023), Stochastic Subgraph Neighborhood Pooling (SSNP; Jacob et al., 2023) and Subgraph-To-Node Translation (S2N; Kim & Oh, 2024). Baseline results are taken from the corresponding research papers.

**Efficiency Measurement** When measuring the complete training time, we run models of the best hyperparameters from each model’s original code, including batch sizes and total epochs, using Intel(R) Xeon(R) CPU E5-2640 v4 and a single GeForce GTX 1080 Ti (for deep GNNs).

**Implementation** All models are implemented with PyTorch (Paszke et al., 2019) and PyTorch Geometric (Fey & Lenssen, 2019). We use the implementation of Support Vector Machines (SVMs) in Scikit-learn (Pedregosa et al., 2011).

## 5 RESULTS AND DISCUSSIONS

In this section, we compare the classification performance and efficiency of WLKS and baselines. In addition, the performance of WLKS according to  $\mathbb{K}$  is demonstrated to exhibit the usefulness of the kernel combination. Finally, we investigate how structure and features across subgraph datasets affect downstream performance by fusing WLKS and GNNs.

**Performance and Efficiency** In Table 2, the classification performance of WLKS- $\{0, D\}$  and baselines on eight datasets is summarized. Our results show that our model outperforms the best-performing baseline in five out of eight datasets. Specifically, WLKS- $\{0, D\}$  achieves the highest micro F1-score on PPI-BP, EM-User, Density, Coreness, and Component. For HPO-Neuro, HPO-Metab, and Cut-Ratio, our model shows similar performance to SubGNN but relatively lower performance than the state-of-the-art model.

In terms of efficiency, we present the total training time of our model and four representative baselines on real-world datasets in Table 3. Note that an experiment on PPI-BP with SubGNN cannot be conducted since it takes more than 48 hours in pre-computation. WLKS- $\{0, D\}$  demonstrates significantly faster training times across all real-world datasets compared to other models (e.g., the

Table 4: Mean performance of WLKS- $\mathbb{K}$  in micro F1-score by  $\mathbb{K}$ :  $\{0\}$ ,  $\{1\}$ ,  $\{2\}$ ,  $\{D\}$ , and  $\{0, D\}$ . The standard deviations are omitted (all 0). The higher the performance, the darker the blue color.

Model	PPI-BP	HPO-Neuro	HPO-Metab	EM-User	Density	Cut-Ratio	Coreness	Component

WLKS- $\{D\}$	64.2	65.1	57.9	89.8	68.0	56.0	39.1	100.0

Table 5: Mean performance in micro F1-score of S2N models with kernel matrix  $\mathbf{K}_{\text{WLS}}-\{0, D\}$  as adjacency matrix between subgraphs over 10 runs. S2N models are based on GCNII. The higher the performance, the darker the blue color.

Model	PPI-BP	HPO-Neuro	HPO-Metab	EM-User	Density	Cut-Ratio	Coreness	Component
S2N+0	63.5 $\pm$ 2.4	66.4 $\pm$ 1.1	61.6 $\pm$ 1.7	86.5 $\pm$ 3.2	67.2 $\pm$ 2.4	56.0 $\pm$ 0.0	57.0 $\pm$ 4.9	100.0 $\pm$ 0.0
S2N+A	63.7 $\pm$ 2.3	68.4 $\pm$ 1.0	63.2 $\pm$ 2.7	89.0 $\pm$ 1.6	93.2 $\pm$ 2.6	56.0 $\pm$ 0.0	85.7 $\pm$ 5.8	100.0 $\pm$ 0.0
WLKS- $\{0, D\}$	64.8 $\pm$ 0.0	65.3 $\pm$ 0.0	57.9 $\pm$ 0.0	91.8 $\pm$ 0.0	96.0 $\pm$ 0.0	60.0 $\pm$ 0.0	91.3 $\pm$ 0.0	100.0 $\pm$ 0.0
WLKS- $\{0, D\}$ for S2N+0	64.8 $\pm$ 1.5	66.3 $\pm$ 0.6	62.4 $\pm$ 1.1	86.5 $\pm$ 2.4	92.0 $\pm$ 0.0	51.2 $\pm$ 3.9	69.6 $\pm$ 1.9	100.0 $\pm$ 0.0
WLKS- $\{0, D\}$ for S2N+A	65.4 $\pm$ 2.4	68.4 $\pm$ 1.1	62.9 $\pm$ 1.9	90.0 $\pm$ 3.3	95.6 $\pm$ 2.8	48.0 $\pm$ 0.0	87.4 $\pm$ 4.1	100.0 $\pm$ 0.0

shorter training time of  $\times 0.01$  on HPO-Neuro,  $\times 0.17$  on HPO-Metab,  $\times 0.38$  on EM-User,  $\times 0.53$  on PPI-BP). This metric does not include the pre-computation or embedding pretraining required in baselines, so the actual training of WLKS is more efficient. Additionally, WLKS does not require a GPU, unlike other GNN baselines.

**Performance of WLKS- $\mathbb{K}$  by  $\mathbb{K}$**  We highlight the importance of selecting the appropriate  $\mathbb{K}$  in Table 4. Specifically, the performance of WLKS- $\mathbb{K}$  varies significantly depending on the choice of  $\mathbb{K}$ . WLKS- $\{0, D\}$ , which combines kernels of 0 and  $D$ , consistently delivers strong results across datasets. WLKS- $\{0\}$  and WLKS- $\{D\}$  perform well independently in certain datasets, but their combination makes the better performance. This result suggests that multiple  $k$ -hop neighborhoods are associated with the labels of the subgraph, and the performance can be improved from the complementary nature of WLKS capturing different  $k$ -hop structures.

**Performance of GNNs with the WLKS Kernel Matrix as Adjacency Matrix** In Table 5, we present the results of fusing WLKS- $\{0, D\}$  and GNNs (i.e., S2N). The performance of the WLKS- $\{0, D\}$  for S2N improves over vanilla WLKS- $\{0, D\}$  on PPI-BP, HPO-Neuro, and HPO-Metab, however, performance drops on EM-User, Density, Cut-Ratio, and Coreness. Note that applying GNNs to the WLKS kernel matrix requires kernel sparsification, leading to a loss of structural information. However, this trade-off can be offset by the enhanced features of neural networks. For subgraph-level tasks, we interpret that the former set of benchmarks prioritizes features over structure, while the latter relies more on structural information.

In addition, the performance of WLKS for S2N improves over or is similar to the original S2N across all datasets except for Cut-Ratio. The original S2N uses edge weights based on the number of common nodes between subgraphs. This indicates that the structural similarity, as captured by the kernel matrix, is more important than node membership information for most subgraph benchmarks.

**Sensitivity Analysis of Hyperparameters** Figures 3 and 4 demonstrate the performance sensitivity of the WLKS- $\{0, D\}$  with respect to the number of iterations  $T$  and the kernel mixing coefficient  $\alpha_0$ . The best performance is achieved at iterations of  $T = 2$  or  $T = 3$ , beyond which the WL coloring stabilizes and no further improvement is observed. For  $\alpha_0$ , the WLKS- $\{0, D\}$  is best-performed between  $10^{-3}$  and  $10^{-1}$ , while performance drops sharply as  $\alpha_0$  approaches 1. Since  $\alpha_D = 1 - \alpha_0$  is larger than  $\alpha_0$  in this range, this suggests that the subgraph labels rely more on global structures ( $k = D$ ) than internal ones ( $k = 0$ ).

Figure 3: Performance of WLKS- $\{0, D\}$  by the number of iterations  $T$ .Figure 4: Performance of WLKS- $\{0, D\}$  by the coefficient  $\alpha_0$  in  $\alpha_0 \mathbf{K}_{\text{WLS}}^0 + (1 - \alpha_0) \mathbf{K}_{\text{WLS}}^D$ .

## 6 CONCLUSION

We proposed WLKS, a simple but powerful model for subgraph-level tasks that generalizes the Weisfeiler-Lehman (WL) kernel on induced  $k$ -hop neighborhoods. WLKS can enhance expressiveness by linearly combining kernel matrices from multiple  $k$ -hop levels, capturing richer structural information without redundant neighborhood sampling. Through extensive experiments on eight real-world and synthetic benchmarks, WLKS outperformed state-of-the-art methods on five datasets with reduced training times—ranging from  $\times 0.01$  to  $\times 0.53$  compared to existing models. Furthermore, WLKS does not need pre-computation, pre-training, GPUs, or extensive hyperparameter tuning.

Our method offers a promising and accessible alternative to GNN-based approaches for subgraph representation learning, but some tasks can still benefit from deep neural networks. We leave as future work the seamless integration of WLKS with GNNs to leverage the expressive power of both structures and features.
