NOISE PROMPT LEARNING: LEARNING THE WINNING TICKETS FOR DIFFUSION SAMPLING

Anonymous authors

Paper under double-blind review

ABSTRACT

Text-to-image diffusion model is a popular paradigm that synthesizes personalized images by providing a text prompt and a random Gaussian noise. While people observe that some noises are winning tickets that can achieve better textimage alignment and higher human preference than others, we still lack a machine learning framework to obtain those winning noises. To learn winning noises for diffusion sampling, we mainly make three contributions in this paper. First, we identify a new concept termed the *noise prompt*, which aims at turning a random Gaussian noise into a winning noise ticket by adding a small desirable perturbation derived from the text prompt. Following the concept, we first formulate the noise prompt learning framework that systematically learns "prompted" winning noise tickets associated with a text prompt for diffusion models. Second, we design a noise prompt data collection pipeline and collect a large-scale *noise prompt* dataset (NPD) that contains 100k pairs of random noises and winning noises with the associated text prompts. With the prepared NPD as the training dataset, we trained a small *noise prompt network* (NPNet) that can directly learn to transform a random noise ticket into a winning noise ticket. The learned winning noise perturbation can be considered as a kind of prompt for noise, as it is rich in semantic information and tailored to the given text prompt. Third, our extensive experiments demonstrate the impressive effectiveness and generalization of NPNet on improving the quality of synthesized images across various diffusion models, including SDXL, DreamShaper-x1-v2-turbo, and Hunyuan-DiT. Moreover, NPNet is a small and efficient controller that acts as a plug-and-play module with very limited additional inference and computational costs, as it just provides a winning noise instead of a random noise without accessing the original pipeline.

1 INTRODUCTION

Image synthesis that are precisely aligned with given text prompts remains a significant challenge for text-to-image (T2I) diffusion models (Betker et al.; Chen et al., 2023; Rombach et al., 2022b; Peebles & Xie, 2023; Pernias et al., 2023). Previous studies (Yu et al., 2024; Wu et al., 2022; Toker et al., 040 2024; Kolors, 2024) have investigated the influence of text embeddings on the synthesized images 041 and leveraged these embeddings for training-free image synthesis. It is well known that text prompts 042 significantly matter to the quality and fidelity of the synthesized images. However, image synthesis 043 is induced by both the text prompts and the noise. Variations in the noise can lead to substantial 044 changes in the synthesized images, as even minor alterations in the noise input can dramatically influence the output (Xu et al., 2024; Qi et al., 2024). This sensitivity underscores the critical role that noise plays in shaping the final visual representation, affecting both the overall aesthetics and 046 the semantic faithfulness between the synthesized images and the provided text prompt. 047

Recent studies (Lugmayr et al., 2022; Guo et al., 2024; Chen et al., 2024; Qi et al., 2024; Chefer et al., 2023) observe that some selected or optimized noises are winning tickets that can help the T2I diffusion models to produce images of better semantic faithfulness with text prompts, and can also improve the overall quality of the synthesized images. These methods (Chefer et al., 2023; Guo et al., 2024) incorporate extra modules like attention to reduce the truncate errors during the sampling process, showing promising results on the compositional generalization task. However, they are often not widely adopted in practice for several reasons. First, they often struggle to generally

Figure 1: We visualize images synthesized by 3 different diffusion models and evaluate them using 6 human preference metrics. Images for each prompt are synthesized using the same random seed. These images with NPNet demonstrate a noticeable improvement in overall quality, aesthetic style, and semantic faithfulness, along with numerical improvements across all six metrics. More importantly, our NPNet is applicable to various diffusion models, showcasing strong generalization performance with broad application potential. More visualization results are in Appendix 14.

076

transfer to various benchmark datasets or diffusion models but only work for some specific tasks.
 Second, these methods often introduce significant time delays in order to optimize the noises during
 the reverse process. Third, they require in-depth modifications to the original pipelines when applied
 to different T2I diffusion models with varying architectures. Fourth, they need specific subject
 tokens for each prompt to calculate the loss of certain areas, which are unrealistic requirements
 for real users. These not only significantly complicate the original inference pipeline but also raise
 concerns regarding the generalization ability across various T2I diffusion models and datasets.

- In light of the aforementioned research, we pose several critical questions: 1) Can we formulate
 obtaining the winning noise tickets as a machine learning problem so that we can predict them
 efficiently with only one model forward inference? 2) Can such a machine learning framework
 generalize well to various noises, prompts, and even diffusion models? Fortunately, the answers are
 affirmative. In this paper, we mainly make three contributions:
- First, we identify a new concept termed *noise prompt*, which aims at turning a random noise into a winning noise ticket by adding a small desirable perturbation derived from the text prompt. The winning noise perturbation can be considered as a kind of prompt for noise, as it is rich in semantic information and tailored to the given text prompt. Building upon this concept, we first formulate a *noise prompt learning* framework that systematically learns "prompted" winning noise tickets associated with text prompts for diffusion models.
- Second, to implement the formulated *noise prompt learning* framework, we propose the training dataset, namely the *noise prompt dataset* (NPD), and the learning model, namely the *noise prompt network* (NPNet). Specifically, we design a noise prompt data collection pipeline via *re-denoise sampling*, a way to produce noise pairs. We also incorporate AI-driven feedback mechanisms to ensure that the noise pairs are highly valuable. This pipeline enables us to collect a large-scale training dataset for noise prompt learning, so the trained NPNet can directly transform a random Gaussian noise into a winning noise ticket to boost the performance of the T2I diffusion model.
- Third, we conduct extensive experiments across various mainstream diffusion models, including
 StableDiffusion-xl (SDXL) (Podell et al., 2023), DreamShaper-xl-v2-turbo and Hunyuan-DiT (Li
 et al., 2024), with 7 different samplers on 3 different datasets. We evaluate our model by utilizing 6 human preference metrics including PickScore (Kirstain et al., 2023), Human Preference

Figure 2: Our workflow diagram consists of three main stages. Stage I: We begin by denoising 123 the original random Gaussian noise \mathbf{x}_T to obtain \mathbf{x}_{T-1} , and then use DDIM-Inversion(\cdot) to obtain 124 inverse \mathbf{x}_T' with more semantic information. Both synthesized images \mathbf{x}_0 and \mathbf{x}_0' are filtered by the 125 human preference model, such as HPSv2, to ensure the dataset is both diverse and representative. 126 Stage II: After collecting NPD, we input the original noise (source noise) x_T , inverse noise (target 127 noise) \mathbf{x}'_T and text prompt c into the NPNet, where the noises are processed by the singular value predictor and the residual predictor, and text prompt c is encoded by the text encoder $\mathcal{E}(\cdot)$ of the 128 T2I diffusion model, resulting in the winning noise ticket. Stage III: Once trained, our NPNet can 129 directly convert the random Gaussian noise into a winning noise ticket before inputting T2I diffusion 130 models, boosting the performance of these models. 131

133 Score v2 (HPSv2) (Wu et al., 2023), Aesthetic Score (AES), ImageReward (Xu et al., 2023), CLIP-134 Score (Hessel et al., 2022) and Multi-dimensional Preference Score (MPS) (Zhang et al., 2024). 135 As illustrated in Fig. 1, by leveraging the learned winning noise tickets, not only is the overall 136 quality and aesthetic style of the synthesized images visually enhanced, but all metrics also show significant improvements, demonstrating the effectiveness and generalization ability of our NPNet. 137 Furthermore, the NPNet is a compact and efficient neural network that functions as a plug-and-138 play module, introducing only a 3% increase in inference time per image compared to the standard 139 pipeline, while requiring approximately 3% of the memory required by the standard pipeline. This 140 efficiency underscores the practical applicability of NPNet in real-world scenarios. 141

2 PRELIMINARIES

We first present preliminaries about DDIM and DDIM Inversion and the classifier-free guidance.Due to the space constraints, we introduce the related work in Appendix B.

Given the Gaussian noise $\epsilon_t \sim \mathcal{N}(0, \mathbf{I})$, we denote the forward process of diffusion models as $\mathbf{x}_t = \alpha_t \mathbf{x}_0 + \sigma_t \epsilon_t$, where the $t \in \{0, 1, \dots, T\}$. Here, α_t and σ_t are predefined noise schedules, and x_0 is the original image.

DDIM and DDIM Inversion. Denoising diffusion implicit model (DDIM) (Song et al., 2023) is an advanced deterministic sampling technique, deriving an implicit non-Markov sampling process of the diffusion model. It allows for faster synthesis while maintaining the quality of synthesized samples. Its reverse process can be formulated as:

$$\mathbf{x}_{t-1} = \text{DDIM}(\mathbf{x}_t) = \alpha_{t-1} \left(\frac{\mathbf{x}_t - \sigma_t \epsilon_\theta(\mathbf{x}_t, t)}{\alpha_t} \right) + \sigma_{t-1} \epsilon_\theta(\mathbf{x}_t, t)$$
(1)

Using DDIM to add noise instead of applying Eq. 1 is called DDIM-Inversion:

$$\mathbf{x}_{t} = \text{DDIM-Inversion}(\mathbf{x}_{t-1}) = \frac{\alpha_{t}}{\alpha_{t-1}} \mathbf{x}_{t-1} + \left(\sigma_{t} - \frac{\alpha_{t}}{\alpha_{t-1}} \sigma_{t-1}\right) \epsilon_{\theta}(\mathbf{x}_{t}, t)$$
(2)

161 **Classifier-free Guidance.** Classifier-free guidance (CFG) (Ho & Salimans, 2021) allows for better control over the synthesis process by guiding the diffusion model towards desired conditions, such

as text prompt, to enhance the quality and diversity of synthesized samples. The predicted noise ϵ_{pred} with CFG at timestep t can be formulated as:

$$\epsilon_{pred} = (\omega + 1)\epsilon_{\theta}(\mathbf{x}_t, t|\mathbf{c}) - \omega\epsilon_{\theta}(\mathbf{x}_t, t|\emptyset), \tag{3}$$

where we denote the c as the text prompt, ω as the CFG scale. Based on this, the denoised image $\mathbf{x_{t-1}}$ by using DDIM(·) can be written as:

$$\mathbf{x}_{t-1} = \alpha_{t-1} \left(\frac{\mathbf{x}_t - \sigma_t \left[(\omega + 1)\epsilon_{\theta}(\mathbf{x}_t, t | \mathbf{c}) - \omega \epsilon_{\theta}(\mathbf{x}_t, t | \varnothing) \right]}{\alpha_t} \right) + \sigma_{t-1} \left[(\omega + 1)\epsilon_{\theta}(\mathbf{x}_t, t | \mathbf{c}) - \omega \epsilon_{\theta}(\mathbf{x}_t, t | \varnothing) \right]$$
(4)

3 NOISE PROMPT LEARNING

In this section, we present the methodology of noise prompt learning, including NPD collection,
 NPNet design and training, as well as sampling with NPNet.

Noise prompt can be considered as a kind of special prompt, which 177 aims at turning a random noise into a winning noise ticket by adding 178 a small desirable perturbation derived from the text prompt. Anal-179 ogous to text prompts, appropriate noise prompts can enable diffu-180 sion models to synthesize higher-quality images that are rich in se-181 mantic information. As illustrated on the left in Fig. 3, text prompt 182 learning in large language models (Liu et al., 2021) focuses on 183 learning how to transform a text prompt into a more desirable ver-184 sion. Similarly, *noise prompt learning* in our work seeks to learn 185 how to convert the random Gaussian noise into the winning noise by adding a small, desirable perturbation derived from the text prompt. Using the winning noise, the diffusion model can synthesize im-187 ages with higher quality and semantic faithfulness. Defining it as 188 a machine learning problem, we are the first to formulate the noise 189 prompt learning framework, as illustrated on the right in Fig. 3. 190 Given the training set $\mathcal{D} := \{\mathbf{x}_{T_i}, \mathbf{x}'_{T_i}, \mathbf{c}_i\}_{i=1}^{|\mathcal{D}|}$ consisting of source

Figure 3: Paradigms of *text* prompt learning and noise prompt learning.

¹⁹¹ Given the training set $\mathcal{D} := \{\mathbf{x}_{T_i}, \mathbf{x}_{T_i}, \mathbf{c}_i\}_{i=1}^{i=1}$ consisting of source noises \mathcal{X} , target noises \mathcal{X}' and text prompts \mathcal{C} , loss function ℓ and the neural network ϕ , the general formula for the *noise prompt learning* task is:

$$\phi^* = \arg\min_{\phi} \mathbb{E}_{(\mathbf{x}_{T_i}, \mathbf{x}'_{T_i}, \mathbf{c}_i) \sim \mathcal{D}} [\ell(\phi(\mathbf{x}_{T_i}, \mathbf{c}_i), \mathbf{x}'_{T_i})].$$
(5)

In summary, our goal is to learn the optimal neural network model ϕ^* trained on the training set \mathcal{D} . We present the data-training-inference workflow diagram with three stages in Fig. 3 and provide the pseudocodes for each stage in Appendix Alg. 1, Alg. 2 and Alg. 3, respectively.

3.1 NOISE PROMPT DATASET COLLECTION

In this subsection, we outline the training data collection pipeline, which consists of collecting noise
 pairs and AI-feedback-based data selection, as shown in Fig. 2 *Stage I*.

Re-denoise Sampling Produces Noise Pairs. How to collect winning noise tickets with desirable 203 semantic information? Meng et al. (2023) reported that adding the random noise at each timestep 204 during the sampling process and then re-denoising, leads to a substantial improvement in the se-205 mantic faithfulness of the synthesized images. This motivated us to propose a simple and direct 206 approach called RE-DENOISE SAMPLING. Instead of directly adding noise to each timestep during 207 the reverse process, we propose to utilize DDIM-Inversion(\cdot) to obtain the noise from the previous 208 step. Specifically, the joint action of DDIM-Inversion and CFG can induce the initial noise to attach 209 semantic information. We denote the CFG scale within DDIM(·) and DDIM-Inversion(·) as ω_l and 210 ω_w , respectively. It is sufficient to ensure that the initial noise can be purified stably and efficiently 211 by \mathbf{x}'_t =DDIM-Inversion(DDIM(\mathbf{x}_t)) with $\omega_l > \omega_w$. Utilizing this method, the synthesized image 212 from \mathbf{x}'_{t} is more semantic information contained with higher fidelity, compared with the synthesized 213 image from \mathbf{x}_t . We call the inverse noise \mathbf{x}'_t target noise, and the noise \mathbf{x}_t source noise. The visualization results are shown in Fig. 4. The mechanism behind this method is that DDIM-Inversion(\cdot) 214 injects semantic information by leveraging the CFG scale inconsistency. We present theoretical 215 understanding of this mechanism in Theorem E.1 with the proof.

216 **Data Selection with the Human Preference Model.** While employing *re-denoise sampling* can 217 help us collect noises with enhanced semantic information, it also carries the risk of introducing 218 extra noises, which may lead to synthesizing images that do not achieve the quality of the origi-219 nals. To mitigate this issue, we utilize a human preference model for data selection. This model 220 assesses the synthesized images based on human preferences, allowing us to retain those noise samples that meet our quality standards. The reservation probability for data selection can be for-221 mulated as $\mathbb{I}[s_0 + m < s'_0]$, where m is the filtering threshold, $\mathbb{I}[\cdot]$, s_0 and s'_0 are the indicator 222 function, human preference scores of denoised images from x_0 and x'_0 , respectively. If the noise samples meet this criterion, we consider them to be valuable noise pairs and proceed to collect them. 224

By implementing this filtering process, we aim to keep a balance between leveraging the benefits of *re-denoise sampling* and maintaining the integrity of the synthesized outputs. For the selection strategies, we introduce them in Appendix Sec. D.1.

228 229 230

248 249 3.2 NOISE PROMPT NETWORK

After data collection, we propose the architecture, training, inference of NPNet, as shown in Fig. 2 *Stage II* and *Stage III*.

Architecture Design. The architecture of NPNet consists of
 two key components, including *singular value prediction* and
 residual prediction, as shown in Fig. 2 *Stage II*.

The first key model component is singular value prediction. We 237 obtain noise pairs through re-denoise sampling, a process that 238 can be approximated as adding a small perturbation to the source 239 noises. We observe that through the singular value decomposi-240 *tion* (SVD), the singular vectors of \mathbf{x}_T and \mathbf{x}'_T exhibit remarkable 241 similarity, albeit possibly in opposite directions, shown in Fig. 5, 242 which may be partly explained by Davis-Kahan Theorem (Stew-243 art, 1990; Xie et al., 2023). Building upon this observation, we 244 design an architecture to predict the singular values of the tar-245 get noise, illustrated in Fig. 2 Stage II. We denote $\phi(\cdot, \cdot, \cdot)$ as a

(a) Standard (b) Inversion

Figure 4: Visualization results about *re-denoise sampling. Redenoise sampling* can help to inject semantic information of the text prompt into the original Gaussian noise, boosting the fidelity of synthesized images.

ternary function that represents the sum of three inputs, $f(\cdot)$ as the linear layer function, and $g(\cdot)$ as the multi-head self-attention layer. The paradigm can be formulated as:

$$\mathbf{x}_T = U \times \Sigma \times V^{\mathsf{T}}, \quad \tilde{\mathbf{x}}_T = \phi(U, \Sigma, V^{\mathsf{T}}), \quad \tilde{\Sigma} = f(g(\tilde{\mathbf{x}}_T)), \quad \tilde{\mathbf{x}}_T' = U \times \tilde{\Sigma} \times V^{\mathsf{T}}, \tag{6}$$

where we denote $\tilde{\mathbf{x}}'_T$ as the predicted target noise. This model utilizes SVD inverse transformation to effectively reconstruct the target noise. By leveraging the similarities in the singular vectors, our model enhances the precision of the target noise restoration process.

The second key model component is residual prediction. In addition to *singular value prediction*, 254 we also design an architecture to predict the residual between the source noise and the target noise, 255 as illustrated in Fig. 2 Stage II. We denote $\varphi(\cdot)$ as the UpSample-DownConv operation, $\varphi'(\cdot)$ as 256 the DownSample-UpConv operation, and the $\psi(\cdot)$ as the ViT model. The target noise incorporates 257 semantic information from the text prompt c introduced through CFG. To facilitate the learning 258 process, we inject this semantic information using the frozen text encoder $\mathcal{E}(\cdot)$ of the T2I diffusion 259 model. This approach allows the model to effectively leverage the semantic information provided by 260 the text prompt, ultimately improving the accuracy of the noise residual prediction. The procedure 261 can be described as follows:

$$\mathbf{e} = \sigma(\mathbf{x}_T, \mathcal{E}(\mathbf{c})) \quad \hat{\mathbf{x}}_T = \varphi'(\psi(\varphi(\mathbf{x}_T + \mathbf{e})), \tag{7}$$

where we denote $\sigma(\cdot, \cdot)$ as AdaGroupNorm to ensure stability during the training process, and e as the normalized text embedding.

Using Collected Dataset for Training. The training procedure is also illustrated in Fig. 2 *Stage II*. To yield optimal results with two model components, we formulate the training loss as

269

262 263

$$\mathcal{L}_{\text{MSE}} = \text{MSE}(\mathbf{x}'_T, \mathbf{x}'_{T_{pred}}), \text{ where } \mathbf{x}'_{T_{pred}} = \tilde{\mathbf{x}}'_T + \beta \hat{\mathbf{x}}_T, \tag{8}$$

Figure 5: Visualization about the similarities between the singular vectors of \mathbf{x}_T and \mathbf{x}'_T . Note that we take the absolute values of the cosine similarity scores, and sort them reversely (the horizontal axis represents the indexes of the singular vectors).

Figure 6: The FID comparison with 5000 images in class-conditional ImageNet with the resolution 512×512 . The results validate the effectiveness of our NPNet on improving the conventional image quality metric.

 β is a trainable parameter used to adaptively adjust the weights of the predicted residuals, and L as the MSE(·) loss function. For the nuanced adjustment in how much semantic information contributes to the model's predictions, $\mathbf{x}'_{T_{pred}} = \tilde{\mathbf{x}}'_T + \beta \hat{\mathbf{x}}_T$ can be rewritten as:

$$\mathbf{x}_{T_{ored}}' = \alpha \mathbf{e} + \tilde{\mathbf{x}}_{T}' + \beta \hat{\mathbf{x}}_{T},\tag{9}$$

where we denote α as a trainable parameter. The values of these two parameters are shown in Appendix Table 13. we notice that α is very small, but it still plays a role in adjusting the influence of injected semantic information (the experimental results are shown in Appendix Table 11). These two parameters, α and β , facilitate a refined adjustment of how much semantic information influences the model's predictions, enabling the semantic relevance between the text prompt and synthesized images, and the diversity of synthesized images.

Insert NPNet for Sampling. The inference procedure is illustrated in Fig. 2 *Stage III*. Once trained, our NPNet can be directly applied to the T2I diffusion model by inputting the initial noise x_T and prompt embedding c encoded by the frozen text encoder of the diffusion model. Our NPNet can effectively transform the original initial noise into the winning noise ticket. We also provide the example code on SDXL, shown in the Appendix Fig. 13.

4 EMPIRICAL ANALYSIS

In this section, we empirically study the effectiveness, the generalization, and the efficiency of our NPNet. We conduct a lot of experiments across various datasets on various T2I diffusion models, including SDXL, DreamShaper-xl-v2-turbo, and Hunyuan-DiT. Due to space constraints, we leave implementation details and additional experiments in Appendix A and D, respectively.

Description of Training and Test Data. We collect our NPD on Pick-a-pic dataset (Kirstain et al., 2023), which contains 1M prompts in its training set. We randomly choose 100k prompts as our training set. For each prompt, we randomly assign a seed value in [0, 1024]. For testing, we use three datasets, including the first 100 prompts from the Pick-a-Pic web application, the first 100 prompts from HPD v2 test set (Wu et al., 2023), and all 200 prompts from DrawBench (Saharia et al., 2022). For more details about the test data, please see in Appendix Fig. 18. We construct three training datasets collected from Pick-a-Pic, with 100k noise pairs, 80k noise pairs, and 600 noise pairs for SDXL, DreamShaper-xl-v2-turbo, and Hunyuan-DiT.

Figure 7: The winning rate comparison on SDXL across 3 datasets, including Pick-a-Pic, Draw Bench and HPD v2 (HPD). The results reveal that our NPNet is the only one that can consistently
 transform random Gaussian noise into winning noise tickets, thereby enhancing the quality of the
 synthesized images, across nearly all evaluated datasets and metrics.

results across all 6 metrics and 3 datasets. We also evaluate our fine-tuned NPNet with Hunyuan-DiT, as shown in Table 2. For Hunyuan-DiT, we directly utilized the NPNet model trained on SDXL-produced NPD and fine-tune it on the Hunyuan-DiT-produced 600 noise pairs. Fine-tuned with only 600 samples, it can still achieve the highest results over the baselines on Hunyuan-DiT.
This highlights the strong cross-model generalizability of our NPNet.

We also show the winning rate (the ratio of winning noise in the test set) on SDXL with our NPNet,
shown in Fig. 7. We present more winning rate experiments of DreamShaper-xl-v2-turbo and
Hunyuan-DiT in Appendix Fig. 10 and Appendix Fig. 15. These results again support that our
NPNet is highly effective in transforming random Gaussian noise into winning noise tickets. In order to validate the effectiveness of our NPNet on improving the conventional image quality metric,
we also calculate the FID (Heusel et al., 2018) of 5000 images on class conditional ImageNet with
resolution 512 × 512 (please see more implementation details in Appendix D), shown in Fig. 6. We

Table 3: We conducted combinatorial experiments with other mainstream methods that can improve the alignment between the text prompts and synthesized images. The results indicate that our approach is orthogonal to these methods, allowing for joint usage to achieve improved performance.

4.2 ANALYSIS OF GENERALIZATION AND ROBUSTNESS

To validate the superior generalization ability of our NPNet, we conduct multiple experiments, covering experiments of cross-dataset, cross-model architecture, various inference steps, various random seed ranges, stochastic/deterministic samplers, and the integration of other methods.

403 Generalization to Various Datasets and Models. Although we trained our NPNets exclusively 404 with the NPDs collected from the Pick-a-Pic dataset, the experimental results presented in Tables 1 405 and 2, and Fig. 7 demonstrate that our model exhibits strong cross-dataset generalization capabilities, 406 achieving impressive results on other datasets as well. In addition to the fine-tuning experiments de-407 tailed in Table 2, we also applied the NPNet trained on NPD collected from SDXL to DreamShaper-408 xl-v2-turbo, evaluating the performance with our NPNet without any fine-tuning. The experiment 409 results are shown in Appendix Table 9. These results indicate promising performance with our 410 NPNet, underscoring the model's capability for cross-model generalization. We also conduct exper-411 iments on noise seed range in Appendix 14, the results demonstrate that our NPNet exhibits strong 412 generalization capabilities across the out-of-distribution random seed ranges.

Generalization to Stochastic/Deterministic Samplers. When collecting NPD on SDXL, we use
the deterministic DDIM sampler. However, whether the NPNet can effectively perform with stochastic samplers is crucial. To investigate our NPNet's performance across various sampling methods,
we evaluated 7 different samplers, using NPNet trained on the NPD collected from SDXL, whose
sampler is DDIM. The results shown in Fig. 8 and Appendix Table 5 suggest that our NPNet is
adaptable and capable of maintaining high performance even when subjected to various levels of
randomness in the sampling process, further validating the generalization of our NPNet.

Orthogonal Experiment. To explore whether our model can be combined with other approaches,
which aim at enhancing the semantic faithfulness of synthesized images, such DPO (Rafailov et al.,
2024) and AYS (Sabour et al., 2024), we conduct combination experiments, shown in Table 3.
Note that AYS only releases the code under the inference step 10, so we conduct the combinatorial
experiment with AYS under the inference step 10. The results indicate that our method is orthogonal
to these works, allowing for joint usage to further improve the quality of synthesized images.

Robustness to the Hyper-parameters. We study how the performance of NPNet is robust to the
hyper-parameters. We first evaluate the performance of our NPNet under various inference steps,
as illustrated in Fig. 9, Appendix Fig. 10, Appendix Fig. 11, and Appendix Fig. 15. These results
highlight the generalization and versatility of our NPNet is robust to the common range of inference
steps. inference steps. Such consistency suggests that the model is well-tuned to adapt to different
conditions, making it effective for a wide range of applications. We also do exploration studies on
the other hyper-parameters, such as batch size, the training epochs, and CFG values in Appendix

Figure 8: We evaluate our NPNet with 7 samplers on SDXL in Pick-a-Pic dataset, including both the
deterministic sampler and stochastic sampler (with a default inference step 50). "NPNet-30" means
the inference step is 30 with NPNet. The red area in the top left corner of the image represents the
results of efficient high-performance methods, while the experimental results of NPNet are nearly
in that same region. It highlights that NPNet is capable of synthesizing higher-quality images with
fewer steps and consuming less time. Moreover, the results demonstrate the generalization ability
of our NPNet across different samplers.

Figure 9: Visualization of performance w.r.t. inference steps on SDXL on Pick-a-Pic dataset. With our NPNet, T2I diffusion models can have superior performance under various inference steps.

Table 10. The studied optimal settings are the batch size with 64, the training epochs with 30, and the CFG value with 5.5. Moreover, we explore the influences of different amounts of training samples, shown in Appendix Table 12.

473 Ablation Studies. We conduct ablation studies about the architecture designs of NPNet in Table 4.
474 The results show that both *singular value prediction* and *residual prediction* contribute to the final
475 optimal results, while the *singular value prediction* component plays a more important role. We also
476 empirically verify the effectiveness of data selection strategies in Appendix Tables 7 and 8.

4.3 EFFICIENCY ANALYSIS AND DOWNSTREAM TASK EXPLORATION

Efficiency Analysis. Given the plug-and-play nature of NPNet, it is essential to discuss the memory consumption and inference latency. Remarkably, our model achieves significant performance improvements even with fewer inference steps and reduced time costs in Fig. 8. Even when operating at the same number of inference steps in Table 5, our model introduces only a 0.4-second delay while synthesizing high-quality images, demonstrating its efficiency. Additionally, Appendix Fig. 16 shows its memory consumption is mere 500 MB, highlighting its resource-friendly design. Our model not only delivers superior results but also exhibit significant application potential and practical value due to the impressive deployment efficiency.

486 Table 5: Experiments on different samplers w.r.t. inference time cost on SDXL. The NPNet trained 487 on noise samples produced by the deterministic sampler DDIM, demonstrates impressive general-488 ization to non-deterministic samplers, incurring only minimal additional time costs.

Exploration of Downstream Task. We explored the potential of integrating NPNet with downstream tasks, specifically by combining it with ControlNet (Zhang et al., 2023) for controlled image synthesis. As a plug-and-play module, our NPNet can be seamlessly incorporated into ControlNet. Visualization results in Appendix Fig. 12 demonstrate that this integration leads to the synthesis of more detailed and higher-quality images, highlighting the effectiveness of our approach.

5 DISCUSSION

508 Although our experimental results have demonstrated the superiority of our method. Limitations. 509 the limitations still exist. As a machine learning framework, our method also faces classic challenges 510 from training data quality and model architecture design. First, noise prompt data quality sets the 511 performance limit of our method. The data quality is heavily constrained by re-denoise sampling 512 and data selection, but lack comprehensive understanding. For example, there exists the potential 513 risk that the proposed data collection pipeline could introduce extra bias due to the AI-feedback-514 based selection. Second, the design of NPNet is still somewhat rudimentary. While ablation studies 515 support each component of NPNet, it is highly possible that more elegant and efficient architectures may exist and work well for the novel noise prompt learning task. Optimizing model architectures 516 for this task still lacks principled understanding and remain to be a challenge. 517

518 **Future Directions.** Our work has various interesting future directions. First, it will be highly 519 interesting to investigate improved data collection methods in terms of both performance and trust-520 worthiness. Second, we will design more streamlined structures rather than relying on a parallel approach with higher performance or higher efficiency. For example, we may directly utilize a pre-521 trained diffusion model to synthesize winning noise more precisely. Third, we will further analyze 522 and improve the generalization of our method, particularly in the presence of out-of-distribution 523 prompts or even beyond the scope of T2I tasks. 524

525

CONCLUSION 6

526 527

528 In this paper, we introduce a novel concept termed the *noise prompt*, which aims to transform random Gaussian noise into a winning ticket noise by incorporating a small perturbation derived from 529 the text prompt. Building upon this, we firstly formulate a *noise prompt learning* framework that sys-530 tematically obtains "prompted" winning tickets associated with a text prompt for diffusion models, 531 by constructing a noise prompt dataset collection pipeline that incorporates HPSv2 to filter our data 532 and designing several backbones for our noise prompt models. Our extensive experiments demon-533 strate the superiority of NPNet, which is plug-and-play, straightforward, and nearly time-efficient, 534 while delivering significant performance improvements. This model possesses considerable applica-535 tion potential and practical significance. We believe that the future application scope of NPNet will 536 be broad and impactful, encompassing video, 3D content, and seamless deployment of real AIGC 537 business products, thereby making a meaningful contribution to the community. 538

540 **Ethics Statement.** We propose NPNet, a lightweight neural network designed to enhance the 541 semantic faithfulness of images generated by various diffusion models, necessitate careful consid-542 eration of several ethical issues. Although NPNet does not directly involve human subjects, we are 543 committed to ensuring that its applications respect user autonomy and promote positive outcomes. 544 We emphasize transparency in our dataset releases, ensuring that all datasets used are ethically sourced and compliant with applicable laws, while actively working to mitigate potential biases 545 inherent in the data. We also prioritize the privacy and security of any data utilized, adhering to 546 data protection regulations to safeguard user information. Given NPNet's significant commercial 547 potential, we strive to apply this technology responsibly, ensuring that its applications yield positive 548 societal benefits. 549

702 A IMPLEMENTATION DETAILS

In this section, we present the benchmarks, evaluation metrics and the relevant contents we used in the main paper to facilitate a comprehensive understanding of our model's performance. This overview will help contextualize our results and provide clarity on how we assessed the effectiveness of our approach.

- A.1 BENCHMARKS
- In our main paper, we conduct experiments across three popular text-to-image datasets.

Pick-a-Pic. Pick-a-Pic (Kirstain et al., 2023) is an open dataset designed to collect user preferences
 for images synthesized from text prompts. The dataset is gathered through a user-friendly web
 application that allows users to synthesize images and select their preferences. Each data sample
 includes a text prompt, two synthesized images, and a label indicating which the user prefers or a
 tie if there is no clear preference. The Pick-a-Pic dataset contains over 500,000 examples covering
 35,000 unique prompts. Its advantage lies in the fact that the data comes from real users, reflecting
 their genuine preferences rather than relying on paid crowd workers

- DrawBench. DrawBench is a newly introduced benchmark dataset designed for in-depth evalua tion of text-to-image synthesis models. It contains 200 carefully crafted prompts categorized into 11
 groups, testing the models' abilities across various semantic attributes, including compositionality,
 quantity, spatial relationships, and handling complex text prompts. The design of DrawBench allows
 for a multidimensional assessment of model performance, helping researchers identify strengths and
 weaknesses in image synthesis. By comparing with other models, DrawBench provides a compre hensive evaluation tool for the text-to-image synthesis field, facilitating a deeper understanding of
 synthesis quality and image-text alignment.

710 711

712

720

HPD v2. The Human Preference Dataset v2 (Wu et al., 2023) is a large-scale, cleanly annotated dataset focused on user preferences for images synthesized from text prompts. It contains 798,090 binary preference choices involving 433,760 pairs of images, aiming to address the limitations of existing evaluation metrics that fail to accurately reflect human preferences. HPD v2 eliminates potential biases and provides a more comprehensive evaluation capability, with data sourced from multiple text-to-image synthesis models and real images.

- For testing, we use these three datasets, including the first 100 prompts subset from the Pick-aPic web application, 100 prompts from HPD v2 test set, and 200 prompts from DrawBench. The detailed information of the test sets is shown in Fig. 18.
- 738 739 740
- A.2 EVALUATION METRICS
- In our main paper, we mainly include 6 evaluation metrics to validate the effectiveness of our NPNet.
- 741 742

PickScore. PickScore is a CLIP-based scoring function trained from the Pick-a-Pic dataset, which
 collects user preferences for synthesized images. It achieves superhuman performance when predicting user preferences. PickScore aligns well with human judgments, and together with Pick-a-Pic's
 natural distribution prompts, enables much more relevant text-to-image model evaluation than evaluation standards, such as FID (Heusel et al., 2018) over MS-COCO (Lin et al., 2015).

748

HPSv2. Human Preference Score v2 (HPSv2) is an advanced preference prediction model by finetuning CLIP (Radford et al., 2021) on Human Preference Dataset v2 (HPD v2). This model aims to
align text-to-image synthesis with human preferences by predicting the likelihood of a synthesized
image being preferred by users, making it a reliable tool for evaluating the performance of text-toimage models across diverse image distribution.

754

AES. Aesthetic Score (AES) are derived from a model trained on the top of CLIP embeddings with several extra multilayer perceptron (MLP) layers to reflect the visual appeal of images. This

metric can be used to evaluate the aesthetic quality of synthesized images, providing insights into how well they align with human aesthetic preferences.

ImageReward. ImageReward (Xu et al., 2023) is a human preference reward model specifically designed for evaluating text-to-image synthesis. It is trained on a large dataset of human comparisons, allowing it to effectively encode human preferences. The model assesses synthesized images based on various criteria, including alignment with the text prompt and overall aesthetic quality.
ImageReward has been shown to outperform traditional metrics like Inception Score (IS) (Barratt & Sharma, 2018) and Fréchet Inception Distance (FID) in correlating with human judgments, making it a promising automatic evaluation metric for text-to-image synthesis.

766

CLIPScore. CLIPScore (Hessel et al., 2022) leverages the capabilities of the CLIP model, which aligns images and text in a shared embedding space. By calculating the cosine similarity between the image and text embeddings, CLIPScore provides a mearsure of how well a synthesized image corresponds to its textual description. While CLIPScore is effective in assessing text-image alignment, it may not fully capture the nuances of human preferences, particularly in terms of aesthetic quality and detail.

773 **MPS.** Multi-dimensional Preference Score (MPS) (Zhang et al., 2024), the first multi-dimensional 774 preference scoring model for the evaluation of text-to-image models. The MPS introduces the pref-775 erence condition module upon CLIP model to learn these diverse preferences. It is trained based on 776 the Multi-dimensional Human Preference (MHP) Dataset, which comprises 918,315 human pref-777 erence choices across four dimensions, including aesthetics, semantic alignment, detail quality and 778 overall assessment on 607,541 images, providing a more comprehensive evaluation of synthesized 779 images. MPS calculates the preference scores between two images, and the sum of the two prefer-780 ence scores equals 1.

781 782

783

A.3 T2I DIFFUSION MODELS

In the main paper, we totally use 3 T2I diffusion models, including StableDiffusionxl (SDXL) (Podell et al., 2023), DreamShaper-xl-v2-turbo (DreamShaper), and HunyuanDiT (DiT) (Li et al., 2024).

787

 StableDiffusion-xl. StableDiffusion-xl (SDXL) is an advanced generative model, building upon the original Stable Diffusion architecture. This model leverages a three times larger UNet backbone, and utilizes a refinement model, which is used to improve the visual fidelity of samples synthesized by SDXL using a post-hoc image-to-image technique. SDXL is designed to synthesize highresolution images from text prompts, demonstrating significant improvements in detail, coherence, and the ability to represent complex scenes compared to its predecessors.

793 794

DreamShaper-xl-v2-turbo. DreamShaper-xl-v2-turbo, a fine-tuned version on SDXL, is a textto-image model designed for high-quality image synthesis, focusing on faster inference time and enhanced image synthesis capabilities. DreamShaper-xl-v2-turbo maintains the high-quality image output characteristic of its predecessor, while its turbo enhancement allows for quicker synthesis cycles. The overall style of the synthesized images leans towards fantasy, while it achieves a high level of authenticity when realism is required.

800

Hunyuan-DiT. Hunyuan-DiT is a text-to-image diffusion transformer with fine-grained under standing of both English and Chinese. With careful design of the model architecture, it can perform
 multi-turn multimodal dialogue with users to synthesized high-fidelity images, under the refinement
 of the Multimodal Large Language Model.

805

806 A.4 Hyper-parameter Settings 807

Our method is straightforward and intuitive, and the parameter settings for the entire experiment are also very simple, with epoch 30, and batch size 64 for all experiments. We conduct experiments on three T2I diffusion models, including SDXL, DreamShaper-xl-v2-turbo, and Hunyuan-DiT, with 810 CFG ω_l 5.5, 3.5, and 5.0 respectively. The inverse CFG ω_w is 1.0 for all three models. To col-811 lect training data, the inference steps are 10, 4, and 10 for SDXL with DDIM inverse scheduler, 812 Dreamshaper-xl-v2-turbo with DPMSolver inverse scheduler, and Hunyuan-DiT with DDIM in-813 verse scheduler, respectively. The human preference model we use to filter the data is the HPSv2, 814 and the filtering threshold k equals 0. Unless otherwise specified, all quantitative experiments and synthesized images in this paper are conducted and synthesize with inference steps 50, respectively. 815 All experiments are conducted using $1 \times RTX$ 4090 GPUs, and all these noise pairs are collected 816 with inference step 10 to construct NPDs. 817

818 819

820

B RELATED WORK

Synthesizing images that are precisely aligned with given text prompts remains a significant challenge for Text-to-Image (T2I) diffusion models. To deal with this problem, several works explore training-free improvement strategies, by optimizing the noises during the diffusion reverse process.

Lugmayr et al. (2022) utilizes a pre-trained unconditional diffusion model as a generative prior and alters the reverse diffusion iterations based on the unmasked regions of the input image. Meng et al. (2023) observe that denoising the noise with inversion steps can generate better images compared with the original denoising process. Based on that, Qi et al. (2024) aims to reduce the truncate errors during the denoising process, by increase the cosine similarity between the initial noise and the inversed noise in an end-to-end way. It introduces significant time costs, and the synthesized images may be over-rendered, making it difficult to use in practical scenarios.

Another research direction introduces extra modules to help optimize the noises during the reverse process. Chefer et al. (2023) introduce the concept of Generative Semantic Nursing (GSN), and slightly shifts the noisy image at each timestep of the denoising process, where the semantic information from the text prompt is better considered. InitNO (Guo et al., 2024) consists of the initial latent space partioning and the noise optimization pipeline, responsible for defining valid regions and steering noise navigation, respectively. Such methods are not universally applicable, we discuss this in Appendix C

Table 6: Comparison results with InitNO on StableDiffusion-v1-4 (Rombach et al., 2022a) on
Pick-a-Pic dataset. We directly apply NPNet trained for SDXL, and remove the embedding e to
StableDiffusion-v1-4.

	PickScore (↑)	HPSv2 (\uparrow)	AES (†)	ImageReward (↑)
Standard	19.1732	0.1949	5.4575	-1.2273
InitNO	16.5039	0.1447	5.3116	-2.0566
NPNet (ours)	19.2474	0.1954	5.5151	-0.9589

Unlike previous approaches, we are the first to reframe this task as a learning problem. we directly learn to prompt the initial noise into the winning ticket noise to address this issue, by training a universal Noise prompt network (NPNet) with our noise prompt dataset (NPD). Our NPNet operates as a plug-and-play module, with very limited memory cost and negligible inference time cost, produce images with higher preference scores and better alignment with the input text prompts effectively.

854

C DISCUSSION WITH THE PREVIOUS WORKS

855 We previously mentioned that these methods (Chefer et al., 2023; Guo et al., 2024) optimize the 856 noise during the reverse process by incorporating additional modules. These methods have shown 857 promising results in tasks involving compositional generalization. However, these methods often 858 struggle to transfer to other datasets and models, making them not universally applicable. These 859 approaches require the manual interest subject tokens, necessitating extensive test to identify the op-860 timal tokens for a given sentence, which complicates their application across different datasets. Fur-861 thermore, modifying the model pipeline usually requires in-depth code changes, making it difficult to achieve straightforward plug-and-play integration with other models. Moreover, these methods 862 demand multiple rounds of noise optimization during the reverse process, resulting in significant 863 time consumption.

In contrast, our approach addresses these challenges from multiple perspectives, offering a more
flexible and universal solution. It is capable of cross-model and cross-dataset applications, provides
plug-and-play functionality, and incurs minimal time overhead. The experimental results are shown
in Table. 6. We follow the code in Guo et al. (2024), and manually provide the subject tokens following Chefer et al. (2023). We conduct the experiments on StableDiffusion-v1-4 (Rombach et al.,
2022a) on Pick-a-Pic dataset. We directly apply the NPNet trained for SDXL to StableDiffusionv1-4. The results demonstrate the superiority of our NPNet.

D ADDITIONAL EXPERIMENT RESULTS

D.1 EXPLORATION OF DATA SELECTION STRATEGIES

Since the target noise collected through *re-denoise sampling* is not always of high quality, it is crucial to choose an appropriate method for data filtering. Effective selection ensures that only high-quality noise pairs are used, which is essential for training the NPNet, affecting the model's performance and reliability. For this reason, we conduct experiments on the choice of human preference model to filter our data, shown in Table 7, here the filtering threshold m = 0. The results demonstrate that using HPSv2 ensures data diversity, allowing the filtered data to enhance the model's performance effectively. This approach helps maintain a rich variety of training samples, which contributes to the model's generalization ability and overall effectiveness.

Table 7: To collect valuable samples, we explore the data selection with different human preference models on SDXL with inference steps 10 on Pick-a-Pic dataset. "Standard*" here means no human preference model is applied.

Method	Filter Rate	PickScore (†)	HPSv2 (†)	AES (†)	ImageReward (↑)
Standard*	-	21.2184	0.2595	5.9608	0.4047
PickScore	34.28%	21.2301	0.2590	5.9750	0.3256
HPSv2	23.88%	21.2409	0.2601	5.9675	0.4247
AES	47.62%	21.2195	0.2583	5.9636	0.4323
ImageReward	35.02%	21.2139	0.2570	5.958	0.3239
PickScore+HPSv2	41.93%	21.2298	0.2575	5.9514	0.3859
PickScore+ImageReward	52.57%	21.1413	0.2597	5.9936	0.4219
All	74.41%	21.2100	0.2595	5.9608	0.4047

We also explore the influence under difference filtering thresholds m, the results are shown in Table 8. Our findings reveal that while increasing the filtering threshold m can improve the quality of the training data, it also results in the exclusion of a substantial amount of data, ultimately diminishing the synthesizing diversity of the final NPNet.

Table 8: Experiments on the HPSv2 filtering threshold. We conducted experiments on SDXL on Pick-a-Pic dataset to investigate the impact of adding a threshold during the filtering process, like $s_0 + m < s'_0$, where s_0 and s'_0 are the human preference scores of denoising images \mathbf{x}_0 and \mathbf{x}'_0 .

Threshold	Filter Rate	PickScore (↑)	HPSv2 (†)	AES (†)	ImageReward (↑)
m = 0	23.88%	21.8642	0.2868	6.0540	0.6621
m = 0.005	41.21%	21.7861	0.2879	6.0703	0.6030
m = 0.01	50.19%	21.7219	0.2864	6.0766	0.6160
m = 0.02	83.47%	21.8227	0.2878	6.0447	0.6546

D.2 EVALUATE THE QUALITY OF SYNTHESIZED IMAGES

To validate the quality of the synthesized images with our NPNet, we calculate the FID² of 5000 images in class-conditional ImageNet with the resolution 512×512 on SDXL, shown in Fig. 6. Note

²We follow the code in https://github.com/GaParmar/clean-fid

918 that we just synthesize the "fish" class in the ImageNet dataset, whose directory ids are [n01440764, 919 n01443537, n01484850, n01491361, n01494475, n01496331, n01498041]. The main fish class con-920 tains sub-class labels, including "tench", "Tinca tinca", "goldfish", "Carassius auratus", "great white shark", "white shark", "man-eater", "man-eating shark", "Carcharodon carcharias", "tiger shark", 921 "Galeocerdo cuvieri", "hammerhead", "hammerhead shark", "electric ray", "crampfish", "numb-922 fish", "torpedo", "stingray". Each time, we randomly choose one prompt with postfix "a class in 923 ImageNet", in order to synthesize ImageNet-like images. The results reveal that with our NPNet, 924 the T2I diffusion models can synthesize images with higher quality than the standard ones. 925

926

927 D.3 GENERALIZATION AND ROBUSTNESS

In this subsection, we provide more experiments to validate the generalization ability and robustness of our NPNet.

Table 9: Generalization on different diffusion models. We train our NPNet with NPD collected
 from SDXL. We apply it directly to DreamShaper-xl-v2-turbo on Pick-a-Pic dataset. Our results
 show promising performance, highlighting the model's capability for cross-model generalization.

Inference Steps		PickScore (↑)	HPSv2 (\uparrow)	AES (†)	ImageReward (↑)
1	Standard	21.5790	0.2902	5.9172	0.5312
4	NPNet (ours)	21.6129	0.2920	5.9159	0.5846
10	Standard	22.3961	0.3216	6.0296	0.9667
10	NPNet (ours)	22.4054	0.3224	6.0320	0.9792
30	Standard	22.4235	0.3233	6.0116	0.9897
50	NPNet (ours)	22.4386	0.3248	6.0054	1.0018
50	Standard	22.4168	0.3212	6.0161	0.9809

943 944 945

946

947

948

949

950

951

952 953 **Generalization to Models, Datasets and Inference Steps.** In Table 9, we directly apply the NPNet for SDXL to DreamShaper-xl-v2-turbo without fine-tuning on the corresponding data samples. Even so, our NPNet achieves nearly the best performance across arbitrary inference steps, demonstrating the strong generalization capability of our model. Besides, we also present the winning rate of DreamShaper-xl-v2-turbo and Hunyuan-DiT across 3 different datasets, as presented in Appendix Fig. 10. These experimental results indicate that our method has a high success rate in transforming random Gaussian noise into winning noise, highlighting the effectiveness of our approach.

Generalization to Random Seeds. As we mentioned in Sec. 3.2, the random seed range for the 954 training set is [0, 1024], while the random seed range for the test set is [0, 100]. This discrepancy 955 may lead to our NPNet potentially overfitting on specific random seeds. To evaluate the performance 956 of our NPNet under arbitrary random seeds, we artificially modified the seeds in the test set. The 957 experimental results on the Pick-a-Pic dataset are presented in Table 14, demonstrating that our 958 NPNet maintains strong performance across a variety of random seed conditions, making it suitable 959 for diverse scenarios in real-world applications. The results demonstrate that our NPNet exhibits 960 strong generalization capabilities across the out-of-distribution random seed ranges. 961

Robustness to Inference Steps and Hyper-parameters. In Fig. 11, we conduct the experiments
on DreamShaper-xl-v2-turbo and Hunyuan-DiT under various inference steps. The curve representing our method consistently remains at the top, demonstrating that our model achieves the best
performance across various inference steps, further validating the robustness of our approach. To
further support our claims, we present the winning rate of SDXL, DreamShaper-xl-v2-turbo and
Hunyuan-DiT under various inference in two different datasets, shown in Fig. 15. These promising
results validate the effectiveness of our NPNet.

969

Robustness to Hyper-parameters. We also conduct the experiments on different hyper-parameter
 settings, including the CFG value, batch size and training epochs, shown in Table 10. It reveals that the optimal setting of these parameters are CFG 5.5, batch size 64, and training epoch 30. For all the

experiments in the paper, we all use this setting. Moveover, we explore the influence of the number of training samples, shown in Table 12, we believe that a large dataset can ensure data diversity and improve the model's robustness and generalization ability.

Table 10: Ablation studies of the hyper-parameters on SDXL on Pick-a-Pic dataset.

1013 D.4 EFFICIENCY ANALYSIS AND ABLATION STUDIES

Efficiency Analysis. As a plug-and-play module, it raises concerns about potential increases in inference latency and memory consumption, which can significantly impact its practical value. In addition to Fig. 8 presented in the main paper, we also measure the time required to synthesize each image under the same inference step conditions, shown in main paper Table 5. Our model achieves a significant improvement in image quality with only a 0.4-second inference delay. Additionally, as shown in Fig. 16, our model requires just 500 MB of extra memory. These factors highlight the lightweight and efficient nature of our model, underscoring its broad application potential.

Ablation Studies. We explore the influence of the text embedding term e. Although in Table 13, the value of α is very small, the results in Table 11 still demonstrate the importance of this term. It can facilitate a refined adjustment of how much semantic information influences the model's predictions, enabling the semantic relevance between the text prompt and synthesized images, and the diversity of the synthesized images.

1026 E THEORETICAL SUPPORT OF RE-DENOISE SAMPLING

In main paper Sec. 3.1, we utilize *re-denoise sampling* to produce noise pairs. we propose to utilize DDIM-Inversion(\cdot) to obtain the noise from the previous step. Specifically, the joint action of DDIM-Inversion and CFG can induce the initial noise to attach semantic information. The mechanism behind this method is that DDIM-Inversion(\cdot) injects semantic information by leveraging the guidance scale in classifier-free guidance (CFG) inconsistency:

Theorem E.1. Given the initial Gaussian noise $\mathbf{x}_T \sim \mathcal{N}(0, \mathbf{I})$ and the operators DDIM-Inversion(·) and DDIM(·). Using re-denoise sampling, we can obtain that:

$$\mathbf{x}_{T}' = \mathbf{x}_{T} + \frac{\alpha_{T}\sigma_{T-k} - \alpha_{T-k}\sigma_{T}}{\alpha_{T-k}} \Big[(\omega_{l} - \omega_{w}) (\epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}}, T - \frac{k}{2} | \mathbf{c}) - \epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}}, T - \frac{k}{2} | \varnothing)) \Big].$$
(10)

where k stands for the DDIM sampling step, c is the text prompt, and ω_l and ω_w are CFG at the timestep T and CFG at timestep T-k, respectively.

Proof. One step *re-denoise sampling* represents one additional step forward sampling and one step reverse sampling against the initial Gaussian noise, which can be denoted as

$$\mathbf{x}_{T}' = \text{DDIM-Inversion}(\text{DDIM}(\mathbf{x}_{T})), \tag{11}$$

(12)

where DDIM-Inversion(·) refers to the sampling algorithm in Eqn. 1 when \mathbf{x}_t and \mathbf{x}_{t-1} are interchanged. We can rewrite it in forms of linear transformation:

$$\begin{aligned} \mathbf{x}_{T}^{\prime} &= \alpha_{T} \left(\frac{\mathbf{x}_{T-k} - \sigma_{T-k} \epsilon_{\theta}(\mathbf{x}_{T-k}, T-k)}{\alpha_{T-k}} \right) + \sigma_{T} \epsilon_{\theta}(\mathbf{x}_{T-k}, T-k) \\ \mathbf{x}_{T}^{\prime} &= \alpha_{T} \left(\frac{\alpha_{T-k} \left(\frac{\mathbf{x}_{T} - \sigma_{T} \epsilon_{\theta}(\mathbf{x}_{T}, T)}{\alpha_{T}} \right) + \sigma_{T-k} \epsilon_{\theta}(\mathbf{x}_{T}, T) - \sigma_{T-k} \epsilon_{\theta}(\mathbf{x}_{T-k}, T-k)}{\alpha_{T-k}} \right) + \sigma_{T} \epsilon_{\theta}(\mathbf{x}_{T-k}, T-k) \\ \mathbf{x}_{T}^{\prime} &= \mathbf{x}_{T}^{\prime} - \sigma_{T} \epsilon_{\theta}(\mathbf{x}_{T}, T) + \frac{\alpha_{T} \sigma_{T-k}}{\alpha_{T-k}} \epsilon_{\theta}(\mathbf{x}_{T}, T) - \frac{\alpha_{T} \sigma_{T-k}}{\alpha_{T-k}} \epsilon_{\theta}(\mathbf{x}_{T-k}, T-k) + \sigma_{T} \epsilon_{\theta}(\mathbf{x}_{T-k}, T-k) \\ \mathbf{x}_{T}^{\prime} &= \mathbf{x}_{T}^{\prime} - \frac{\alpha_{T} \sigma_{T-k} - \alpha_{T-k} \sigma_{T}}{\alpha_{T-k}} \left[\epsilon_{\theta}(\mathbf{x}_{T}, T) - \epsilon_{\theta}(\mathbf{x}_{T-k}, T-k) \right], \end{aligned}$$

1038

1039 1040

1041

1042 1043 1044

where k stands for the DDIM sampling step. Substitute $\epsilon_{\theta}(\mathbf{x}_t, t) = (\omega+1)\epsilon_{\theta}(\mathbf{x}_t, t|\mathbf{c}) - \omega\epsilon_{\theta}(\mathbf{x}_t, t|\varnothing)$ into Eq. 12, we can obtain

$$\mathbf{x}_{T}' = \mathbf{x}_{T}' + \frac{\alpha_{T}\sigma_{T-k} - \alpha_{T-k}\sigma_{T}}{\alpha_{T-k}} \Big[(\omega_{l}+1)\epsilon_{\theta}(\mathbf{x}_{T}, T|\mathbf{c}) - \omega_{l}\epsilon_{\theta}(\mathbf{x}_{T}, T|\varnothing)) - (\omega_{w}+1)\epsilon_{\theta}(\mathbf{x}_{T-k}, T-k|\mathbf{c}) + \omega_{w}\epsilon_{\theta}(\mathbf{x}_{T-k}, T-k|\varnothing)) \Big].$$
(13)

1063 1064 Where ω_l and ω_w refer to the classifier-free guidance scale at the timestep T and the classifierfree guidance scale at timestep T - k, respectively. c stands for the text prompt (*i.e.*, condition). Consider the first-order Taylor expansion $\epsilon_{\theta}(\mathbf{x}_{T-k}, T-k|\mathbf{c}) = \epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}}, T-\frac{k}{2}|\mathbf{c}) + \epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}}, T-\frac{k}{2}|\mathbf{c})$ 1067 $\frac{\mathbf{x}_{T-k}-\mathbf{x}_{T-\frac{k}{2}}}{2}\frac{\partial\epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}},T-\frac{k}{2}|\mathbf{c})}{\partial\mathbf{x}_{T-\frac{k}{2}}} + \frac{k}{2}\frac{\partial\epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}},T-\frac{k}{2}|\mathbf{c})}{\partial T-\frac{k}{2}} + \mathcal{O}(\left(\frac{k}{2}\right)^{2}) \text{ and } \epsilon_{\theta}(\mathbf{x}_{T},T|\mathbf{c}) = \epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}},T-\frac{k}{2}|\mathbf{c}) + \mathcal{O}(\left(\frac{k}{2}\right)^{2}) + \mathcal{O}(\left(\frac{$ 1068 1069 $\frac{\mathbf{x}_{T}-\mathbf{x}_{T-\frac{k}{2}}}{2}\frac{\partial\epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}},T-\frac{k}{2}|\mathbf{c})}{\partial\mathbf{x}_{T-\frac{k}{2}}} - \frac{k}{2}\frac{\partial\epsilon_{\theta}(\mathbf{x}_{T-\frac{k}{2}},T-\frac{k}{2}|\mathbf{c})}{\partial T-\frac{k}{2}} + \mathcal{O}(\left(\frac{k}{2}\right)^{2}), \text{ when } \mathbf{x}_{T} \text{ satisfies the condition}$ 1070 1071 $\left\|\frac{\|\|\mathbf{x}_T - \mathbf{x}_{T-k}\|\|}{k}\right\| \le L$, where $L < +\infty$, Eq. 13 can be transformed into: 1072 1073 $\mathbf{x}_T' = \mathbf{x}_T' + \frac{\alpha_T \sigma_{T-k} - \alpha_{T-k} \sigma_T}{\alpha_{T-k}} \Big[(\omega_l - \omega_w) (\epsilon_\theta (\mathbf{x}_{T-\frac{k}{2}}, T - \frac{k}{2} | \mathbf{c}) - \epsilon_\theta (\mathbf{x}_{T-\frac{k}{2}}, T - \frac{k}{2} | \varnothing)) \Big].$ 1074 (14)1075 The proof is complete. 1077

By using Eqn. 14, when there is a gap between ω_l and ω_w , *re-denoise sampline* can be considered as a technique to inject semantic information under the guidance of future timestep $(t = T - \frac{k}{2})$ CFG into the initial Gaussian noise.

Figure 11: Visualization of performance w.r.t inference steps on SDXL, DreamShaper-xl-v2-turbo and Hunyuan-DiT on Pick-a-Pic dataset and DrawBench dataset. The results demonstrate the strong generalization ability of our NPNet.

1126Table 11: We explore the influence of text embedding e. The results reveal that text embedding e is1127crucial in *noise prompt learning*, which aims to inject the semantic information into the noise.

	6:	return x ₀

Figure 14: We visualized images synthesized by 3 different diffusion models and evaluated them using 6 human preference metrics. Images for each prompt are synthesized using the same random seed. These images with NPNet demonstrated a noticeable improvement in overall quality, aesthetic style, and semantic faithfulness, along with numerical improvements across all six metrics. More importantly, our NPNet is applicable to various diffusion models, showcasing strong generalization performance with broad application potential.

Table 14: Random seed generalization experiments on SDXL with difference inference steps on Pick-a-Pic dataset. The random seeds of our training set range from [0, 1024], containing the random seeds of our test set. To explore the generalization ability of NPNet on out-of-distribution random seeds, we manually adjust the random seed range of the test set.

Figure 15: The winning rate comparison on SDXL, DreamShaper-xl-v2-turbo and Hunyuan-DiT across 2 datasets, including DrawBench and HPD v2 (HPD). The results reveal that our NPNet is more effective in transforming random Gaussian noise into winning noise tickets in different inference steps across different datasets.

1349 Figure 16: Our NPNet requires only about 500MB, illustrating the light-weight and efficiency of our model.
