# PASTEL : Polarity-Aware Sentiment Triplet Extraction with LLM-as-a-Judge

#### Anonymous ACL submission

#### Abstract

Aspect Sentiment Triplet Extraction (ASTE) is a subtask of Aspect-Based Sentiment Analysis 003 (ABSA) that aims to extract aspect terms, corresponding opinion terms, and their associated sentiment polarities from text. Current end-toend approaches, whether employing Large Language Models (LLMs) or complex neural net-007 800 work structures, struggle to effectively model the complex latent relationships between aspects and opinions. Therefore, in this work, we propose Polarity-Aware Sentiment Triplet Extraction with LLM-as-a-judge (PASTEL), a novel pipeline which decomposes the ASTE 014 task into structured subtasks. We employ finetuned LLMs to separately extract the aspect and opinion terms, incorporating a polarityaware mechanism to enhance opinion extrac-017 tion. After generating a candidate set through the Cartesian product of the extracted aspect and opinion-sentiment sets, we leverage an LLM-as-a-Judge to validate and prune these candidates. Experimental evaluations demonstrate that PASTEL outperforms existing baselines. Our findings highlight the necessity of modular decomposition in complex sentiment analysis tasks to fully exploit the capabilities 027 of current LLMs.

#### 1 Introduction and Related Work

Aspect-Based Sentiment Analysis (ABSA) is a finegrained sentiment analysis task that aims to determine the sentiment polarity associated with specific aspects in a given text (Pontiki et al., 2014). A key subtask of ABSA is Aspect Sentiment Triplet Extraction (ASTE) (Peng et al., 2019), which involves extracting triplets of (aspect term, opinion term, sentiment polarity) from text. ASTE provides a more structured understanding of sentiments beyond document or sentence-level analysis, enabling deeper insights and decision-making from user feedback thereby driving product and service improvements. However, accurately extracting

037

041

these triplets remains a significant challenge due to the complexity of aspect-opinion interactions and the implicit nature of sentiment dependencies in natural language. 042

Several methodologies have been proposed for ABSA and its subtasks, such as sequence tagging (Xu et al., 2020; Yan et al., 2021), sequence-tosequence generation (Naglik and Lango, 2024), table-filling (Zhang et al., 2022), graph-based (Li et al., 2021; Yin and Zhong, 2024; Jian et al., 2025), contrastive learning (Sun et al., 2024) and span classification (Zhao et al., 2020; Xu et al., 2021; Liang et al., 2022). However, these methods have several issues like sensitivity to parsing errors, failure to model long-range dependencies, and struggling with implicit sentiment reasoning

Recently, large language models (LLMs) have demonstrated remarkable performance in ABSA due to their contextual understanding, instructionfollowing and in-context learning abilities (Scaria et al., 2023; Zhang et al., 2023; Yang et al., 2024; Fan et al., 2025). However, despite excelling at Aspect Term Extraction (ATE) and Opinion Term Extraction (OTE), LLMs struggle with structured triplet extraction due to the difficulty in capturing complex latent dependencies between aspect and opinion terms (§A.2.1). Additionally, they often fail to distinguish between aspect and opinion terms, leading to extraction errors (§A.2.2). This highlights the need for a decoupled approach that integrates contextual understanding of LLMs with structured reasoning to enhance triplet extraction accuracy. The argument against such pipelinebased methods is that they ignore the interaction among triplets, which could result in the error propagation. To alleviate this problem we propose the use of an LLM-as-a-Judge to prune the final results, as LLMs have been shown to achieve a high agreement rate with human experts (Zheng et al., 2023; Gu et al., 2024).

To address the challenges of previous methods,

Figure 1: System diagram

we propose **PASTEL** (Polarity-Aware Sentiment Triplet Extraction with LLM-as-a-Judge), an approach that decomposes ASTE into structured subtasks. Our approach consists of:

- Structured Decomposition of ASTE: We first independently extract aspect and opinion terms using task-specific instruction-tuned LLMs.
- Polarity-Aware Opinion Term Extraction (PAOTE): To mitigate the problem of sentiment misclassification, we have introduced a polarity-aware mechanism that improves and refines OTE.

• Triplet Validation with LLM-as-a-Judge: We construct a comprehensive candidate triplets as the Cartesian product of the extracted aspects and opinion-sentiment pairs, which are validated and pruned by an LLM-asa-Judge to ensure higher precision and alignment with human annotations.

#### 1.1 Task Formulation

Let  $S_i$  denote the *i*-th review sentence in the training dataset. Each  $S_i$  includes a set of aspect terms, represented by  $A_i = a_1^i, a_2^i, \ldots, a_m^i$  and their corresponding opinion terms  $O_i = o_1^i, o_2^i, \ldots, o_m^i$ . Each opinion and aspect term is either a set of tokens extracted from the sentence or "none" when no relevant term is present. The sentiment polarities for the aspect terms are denoted by  $SP_i =$  $sp_1^i, sp_2^i, \ldots, sp_m^i$  where  $sp_k^i$  belongs to the set {pos, neg, neu}. The AOSTE task is then formulated as follows:

$$\mathbf{PASTEL}_{\mathrm{ASTE}}(S_i) = [A_j, O_j, SP_j], \quad j \in m$$
(1)

## 2 Proposed Approach

We outline the design of **PASTEL** in Figure 1. Given a sentence, we aim to predict the triplet(s) of aspect, opinion term and polarity. Our approach splits the extraction of aspect and opinion terms into two parallel pipelines. We extract the opinion terms by using an LLM finetuned for the task in a **polarity-aware** manner (§A.3.1), giving us opinion terms corresponding to positive, negative and neutral polarities. We simultaneously extract the aspect terms via another finetuned LLM. This is followed up by computing the Cartesian product of the results of the two pipelines to get a list of triplet candidates. Finally we use an LLM-as-a-judge to prune the list and produce the final triplets. 116

**Polarity-Aware Opinion Term Extraction** (**PAOTE**) The goal of this pipeline is to extract the opinion term set  $O_i$  from each review sentence  $S_i$  and map them with their respective polarity from  $SP_i$  giving us:

$$P_i = \left\{ (sp_k^i, o_k^i) \right\} \tag{2}$$

where  $P_i$  is the set of all opinions-polarity pairs.

Given that  $sp_j^i$  can take on three possible values, separate entries are generated in dataset for each value. If there is more than one opinion present in the sentence corresponding to a sentiment, all of them are concatenated to a list. For instance, consider  $(s_i, \{([o_1], sp_1(positive)), ([o_2], sp_2(negative)\})$ . This entry is expanded to  $(s_i, [o_1], sp_1), (s_i, [o_2], sp_2)$  and  $(s_i, [none], sp_3(neutral))$ , Here none depicts the absence of opinion term corresponding to particular sentiment polarity (For example sentence refer A.2.3).

With this expanded dataset, we finetune the model using task-specific prompts (See Section

LLaMA 3.2 1B	94.18	94.26	86.07	86.63

Table 2: Aspect Term Extraction F1 Scores on the 14Res, 14Lap, 15Res, and 16Res datasets. For full results refer to Table 5.

A.3.1). This prompt includes auxiliary input in the form of sentiment polarity  $sp_j^i$ , and the model's output will be the corresponding opinion term's  $o_1, o_2, ...$  associated with that polarity. This process is iterated over all possible values of  $sp_j^i$  during inference for a given sentence  $S_i$  to construct final prediction set  $P_i$ .

Aspect Term Extraction (ATE) The model is fine-tuned on a dataset consisting of sentences annotated with corresponding aspect terms. During finetuning, model was provided a task-specific prompt along with some contrastive examples following (Scaria et al., 2023) (See section A.3.2). If no relevant aspects present for a given sentence, models outputs *none*. Formally, the task is defined as:

$$A_i = \mathrm{LM}_{\mathrm{ATE}}(S_i)$$

where LM<sub>ATE</sub> refers to the fine-tuned model that performs ATE,  $S_i$  is the input sentence and  $A_i$  is the set of aspect terms.

171Cartesian Product for Candidate SetWe com-172pute cartesian product between the set of extracted173opinion-polarity pairs  $P_i$  and aspect terms  $A_i$  to174generate a candidate triplet set  $T_i$ . The triplets can

be shown as:

$$T_{i} = \{(a_{i}^{k}, o_{i}^{j}, sp_{i}^{j}) \mid a_{i}^{k} \in A_{i}, (o_{i}^{j}, sp_{i}^{j}) \in P_{i}\}$$

**LLM as a Judge** All candidate triplets from  $T_i$  are passed to GPT-40, which evaluates the given sentence  $S_i$  to determine if each triplet has enough supporting evidence. We employ a chain-of-thought prompt template (See Example A.3.3), which frames the task as an entailment problem. LLMs possess implicit and rich commonsense knowledge about the world. Chain-of-Thought prompt improves LLM's ability to access this implicit knowledge (Fei et al., 2023), generating reasoning trace that improves both accuracy and transparency of the output (Saha et al., 2025).

Each triplet is transformed into a natural language query that prompts the model to verify the relationship between the triplets terms. The model is required to assess whether the evidence in the input sentence supports the query. The prompt includes some few shot examples demonstrating the reasoning behind each decision. The LLM's output is further processed to extract triplet terms from the queries it determined to be supported by the sentence.

#### Experiments

We conducted our experiments using the Llama 3.2 (1B) models and evaluated the proposed system component wise for task-specific extraction i.e. the ATE and OTE pipelines, along with the overarching task of ASTE.

For ATE and OTE tasks we have benchmarked the approach against (Zhao et al., 2020).

For ASTE, We compared our pipeline against the performance of GPT-40 in zero-shot and fewshot settings as highlighted in (Sun et al., 2024). Additionally we also evaluated our pipeline against existing methods, such as Span-BART (Yan et al., 2021), ASTE Transformer (Naglik and Lango, 2024), MiniConGTS (Sun et al., 2024), and InstructABSA (Scaria et al., 2023).

**Dataset and Metrics** For the ASTE task, (Peng et al., 2019) introduced a dataset that is an extension of the SemEval 2014 Task (Pontiki et al., 2014; Xu et al., 2020) produced an enhanced version <sup>1</sup> of this dataset, providing distinct triplets for the cases where one opinion span corresponded to two

aspects terms. We evaluate all models using Precision, Recall and F-1 score.

**Triplet Pruning using LLM-as-a-Judge** We experimented with various prompt templates for pruning candidate triplets (Gu et al., 2024). The first prompt type scored each triplet based on the supporting evidence. However, this method was unreliable as the ratings were inconsistent, making it difficult to set a meaningful threshold A.2.4. We then tried a yes/no type of prompt, which was more consistent but lacked reasoning for complex sentences A.2.5. To address this, we incorporated chain of thought along with few shot examples. This approach not only gave stabilized results but also enhanced the model's reasoning, resulting in transparent and accurate pruning.

We conducted experimentation to assess the performance improvements of PAOTE 3.2(LLaMA 3.2 1B) by comparing it against HAST + TOWE (Li et al., 2018) (Fan et al., 2019) and SpanMLT (Zhao et al., 2020). Table[1] highlights the effectiveness of PAOTE outperforming the other models, highlighting the validity of our approach and achieves highest F1 scores.

Table[2] demonstrates that the full finetuning significantly improves accuracy, particularly recall in LLaMA 3.2 (1B) for **ATE** task. Model achieves the highest F1 across all datasets, outperforming Span-MLT(Zhao et al., 2020) and InstructABSA(Scaria et al., 2023).

The results Table[3] indicate **PASTEL** achieve **state-of-the-art performance** across most datasets in ATSE, outperforming existing methodologies.

PASTEL also performs comparably to the ASTE transformer(Naglik and Lango, 2024) on **15Res** dataset, further validating its effectiveness.

255

256

257

258

# 5 Conclusion

We present a **PASTEL**, a novel approach for ASTE 259 using LLMs, which leverages ATE, PAOTE and 260 LLM-as-a-Judge for structured triplet validation. 261 With reference to Table[1] and [2], our approach 262 consistently performs better than benchmarks on 263 both ATE and OTE, showing the effectiveness of 264 full fine-tuning for achieving optimal model per-265 formance. By splitting the pipeline to extract the 266 aspects and opinion terms separately, we are able to 267 mitigate the limitation of LLMs in understanding 268 the syntactic and semantic dependencies between 269 the aspect and opinion terms, ensuring more pre-270 cise extraction of triplets. PASTEL outperforms on 271 majority of the datasets and remains on par with 272 ASTE Transformer on 15Res. Additionally, LLM-273 as-a-Judge effectively prunes noisy candidates gen-274 erated with Cartesian product of the outputs of 275 the two pipelines. We leverage the proficiency 276 of LLMs and Chain-of-Thought reasoning to un-277 derstand natural language and context to ensure 278 coherence of triplet within given sentence. Both 279 modular fine-tuning strategy and LLM-as-a-Judge 280 mechanism contribute significantly to better accu-281 racy, with a better alignment of human annotations. 282 Overall, all of these results verify the impact of our structured pipeline approach, mirroring the need for modular decomposition and LLM-based verifi-285 cation within ASTE applications.

#### 6 Limitations

287

290

317

318

319

321

324

327

331

332

336

Despite its strengths, PASTEL struggles with the cases where proper nouns acts as an Aspect Term as illustrated in example(§A.2.6). This highlights an area of improvement, particularly in refinement of ATE methodologies, to handle such named entities more effectively. Another key limitation of our approach is propagation of error within our pipeline due to decoupled ATE and PAOTE components. Since candidates triplets are produced using Cartesian products of the extracted sets, misclassified aspects or opinions lead to invalid triplets that need to be pruned. While LLM-as-a-Judge(COT) serves as a filtering mechanism, its performance depends on the quality and construction of the prompt.

#### 7 Ethical Considerations

In our experiments, the datasets have primarily focused upon the reviews of the products and services on e-commerce platform and restaurants, which inherently have lower risk of having any offensive content. We have considered datasets that are 307 widely accepted and extensively referenced within the academic community. We have thoroughly reviewed data to scrutinize data for any potential bias 311 against gender, race, and marginalized groups. Despite our precautions ,there might be a possible case that our model generates sentiment assess-313 ments that could be perceived as offensive. In such 314 cases, we reserve the right to limit or modify the 315 use of our technology to prevent misuse.

## A.1 Experimental Setup

We perform all our finetuning experiments on an A100 GPU using SFT trainer <sup>2</sup> for approximately 300 hours. We have experimented across learning rates from 1e-6 to 1e-4, warmup ratio from 0.1 to 0.5. To ensure that the generation is reliable and consistent we kept the temperature of the generation at 0.1 and top k sampling of 1.

## A.1.1 Aspect Extraction

We finetune the Llama 3.2 1B model for 5 epochs using AdamW optimizer with a learning rate of  $2e^{-5}$ 

## A.1.2 Polarity-Aware Opinion Extraction

We finetune the Llama 3.2 1B model for 5 epochs using AdamW optimizer with a learning rate of  $2e^{-5}$ 

#### A.2 Examples

#### A.2.1 Motivation - Correlation failure

With the rise of powerful LLMs, ABSA is a natural problem that these LLMs can be applied to. To verify this, we tested GPT-40 on some examples from the dataset.

A shortcoming of GPT-40 was that it failed to understand the correlation between aspect and opinion terms. An example is shown below to illustrate this issue.

## GPT-40 performance example 1

**Input sentence:** I also enjoy the fact that my MacBook Pro laptop allows me to run Windows 7 on it by using the VMWare program.

Actual triplets: (Windows 7, enjoy, positive), (VMWare program, enjoy, neutral)

**Triplets extracted by GPT-40:** (fact, enjoy, positive), (MacBook Pro, -, neutral),(laptop, -, neutral), (Windows 7, run, neutral), (VMWare program, using, neutral)

#### A.2.2 Motivation - Lack of Distinction

As shown in the below example, GPT-40 could not distinguish between aspect and opinion terms, extracting the same term for both.

## GPT-40 performance example 2

**Input sentence:** it is of high quality , has a killer GUI , is extremely stable , is highly expandable , is bundled with lots of very good applications , is easy to use , and is absolutely gorgeous.

Actual triplets: (quality, high, positive), (GUI, killer, positive), (applications, good, positive), (use, easy, positive)

**Triplets extracted by GPT-40:** (quality, high, positive), (GUI, killer, positive), (stable, stable, positive), (expandable, expandable, positive), (applications, good, positive), (use, easy, positive), (gorgeous, gorgeous, positive)

## A.2.3 Dataset Expansion

As mentioned in the **OTE** section above the original dataset was expanded into three entries for each entry. Here's an example to better illustrate the modifications.

"The food was good, but the service was bad."

In this case the aspect *food* is linked to the *positive* sentiment, while the aspect *service* is linked to *negative* sentiment. If a particular polarity does not match any opinion term **none** entry is created. Thus, corresponding to each sentence there are three entries in training set. The expanded data set looks like:

Entry 1:  $S_1$ ,  $O_1$  = good,  $SP_1$  = positive Entry 2:  $S_1$ ,  $O_2$  = bad,  $SP_2$  = negative 505

Entry 3:  $S_1$ ,  $O_2$  = none,  $SP_2$  = neutral

# A.2.4 Rating Prompt Output example

The rating prompt output was often inconsistent in its rating system, assigning a lower score for valid triplets. Here's an example illustrating this issue.

# Rating Prompt issue example

**Input sentence:** The phone's battery is amazing, but the camera is horrible. The price is a bit too high, but the brand's reliability is top-notch.

Actual triplets: (battery, amazing, positive), (camera, horrible, negative), (brand's relia-

## bility, top-notch, positive)

**Triplets & Ratings extracted by GPT-40:** 

(battery, amazing, positive) - 4, (camera, horrible, negative) - 9, (price, top-notch, negative) - 6, (brand's reliability, top-notch, positive) - 4

(camera, high, positive) - 7

# 512 513

514

515 516 517

518

# A.2.5 Question Answering prompt Output example

The prompt randomly gave incorrect answers for some of the triplets, the prompt lacked transparency and reasoning behind its decision. This is an example showing this issue:

# Question Answering Prompt issue example

**Input sentence:** The phone's battery is amazing, but the camera is horrible. The price is a bit too high, but the brand's reliability is top-notch.

Actual triplets: (battery, amazing, positive), (camera, horrible, negative), (brand's reliability, top-notch, positive)

**Triplets & Ratings extracted by GPT-40:** (battery, amazing, positive) - Yes,

(camera, horrible, negative) - Yes, (price, top-notch, negative) - Yes, (brand's reliability, top-notch, positive) - No

#### A.2.6 Error Example PASTEL

The PASTEL approach sometimes struggles with identifying proper nouns as aspects, Here's an example highlighting this error:

# PASTEL Error example

**Input sentence:** Servers are all different, Greg is my favorite.

Actual triplets: (Greg, favorite, positive)

Output:

No Valid triplets

#### A.3 Prompts

# A.3.1 Opinion Extraction

The prompt for extracting opinion terms consists of instructions that the model must adhere to. This prompt is prefixed to the input sentence. Finally, the model is given an output format to follow, which makes processing of results easier for the subsequent steps in the pipeline. The main point in the instructions is that, the model is instructed to identify terms that correspond to a certain polarity. A prompt is created for each polarity value (positive, negative and neural) for each sentence. This polarity aware method of prompting helps the

model to identify associated opinion terms by narrowing down the possible opinion terms.

# **Opinion Extraction Prompt**

**Prompt:** Task: Extract all opinion phrases contributing to a *<***POLARITY***>* sentiment from the given sentence. **Instructions:** 

- Identify all the phrases responsible for the *<POLARITY>* sentiment in the sentence.
- 2. Do not explain the output.
- 3. Provide only the extracted phrases in the output.

**Input:** <*SENTENCE*>

**Output:** <*OPINION*<sub>1</sub>, POLARITY>, ...

## A.3.2 Aspect Extraction

Similar to the previous prompt, the prompt used for aspect extraction task also includes some instructions, the input sentence and the output format. In addition to that, some contrastive examples are also provided to guide the model. The examples are contrastive because one example is associated with positive sentiment, one with negative and one with neutral. This helps the model in better disambiguation and also avoids bias towards frequent aspect terms that appear with a certain sentiment.

## Aspect Extraction Prompt

#### Prompt:

Definition: Given a sentence, you must extract the explicit aspects which have an associated opinion. In cases where there are no aspects, the output should be **none**.

#### **Positive Examples:**

1. **Input:** I charge it at night and skip taking the cord with me because of the good battery life.

**Output:** battery life

2. **Input:** I even got my teenage son one, because of the features that it offers, like, iChat, Photobooth, garage band and more!. **Output:** features, iChat, Photobooth, garage band

**Negative Examples:** 1. Input: Speaking of the browser, it too has problems. Output: browser 2. Input: The keyboard is too slick. Output: keyboard **Neutral Examples:** 1. Input: I took it back for an Asus and same thing- blue screen which required me to remove the battery to reset. **Output:** battery 2. Input: Nightly my computer defrags itself and runs a virus scan. **Output:** virus scan Now complete the following example: Input: """<SENTENCE>""" **Output:** <ASPECT\_1>, ...

# A.3.3 LLM as Judge

The prompt for this section consists of the input sentence and triplets in the form of the sentence. The triplets are provided in the form of sentences to utilize LLM's context understanding abilities. The LLM is instructed to attach yes to each triplet sentence that is valid and no otherwise. Some few shot examples are also provided to help the LLM understand the input and output.

# Prompt Example

**prompt structure** = """ Task: Given an input sentence and a list of queries, your task is to determine whether a given query can be entailed from the input sentence, ensuring that there is enough evidence to support the entailment, Here's an example:

<Few shot example>

Input Sentence: <Input Sentence>

Query: Verify if the sentence expresses a "<Sentiment1>" sentiment toward "<Aspect1>" solely based on the use of the opinion term "<Opinion1>". Reasoning:

Table 7: Dataset statistics for 4 datasets (#S - number of sentences, #+, #0 and #- number of positive, neutral and negative triplets respectively.)

Query: Verify if the sentence expresses a<br/>"<Sentiment2>" sentiment toward "<As-<br/>pect2>" solely based on the use of the<br/>opinion term "<Opinion2>". Reasoning:Query: Ver<br/>"positive" sa<br/>solely based<br/>"decent". H<br/>sauce is dirac<br/>conveys a<br/>opinion con<br/>the right po<br/>the output iQuery: Verify if the sentence expresses<br/>a "<SentimentN>" sentiment toward<br/>"<AspectN>" solely based on the use of the<br/>opinion term "<OpinionN>". Reasoning:Query: Ver<br/>"guery: Verify if<br/>the sentence expresses<br/>a "<SentimentN>" sentiment toward<br/>"solely based on the use of the<br/>opinion term "<OpinionN>". Reasoning:Query: Ver<br/>a "positive" sa<br/>solely based<br/>the output is<br/>solely based on the use of the<br/>opinion term "<OpinionN>". Reasoning:Output must be in this format for each<br/>query: Query: Reasoning: """Query: Ver<br/>a "positive" sa<br/>solely based<br/>the output is<br/>solely based<br/>solely based<br/>solely based<br/>solely based<br/>solely based<br/>solely based<br/>solely based<br/>solely based<br/>solely based<br/>"decent". R<br/>as okay, no<br/>sentiment.

Input Sentence: "The Alfredo sauce was decent, the salad was okay, and the dessert

options were quite limited ."

Query: Verify if the sentence expresses a "positive" sentiment toward "Alfredo sauce" solely based on the use of the opinion "decent". Reasoning: The aspect Alfredo sauce is directly described by decent, which conveys a positive sentiment. Since the opinion correctly modifies the aspect with the right polarity, this triplet is valid. Thus, the output is 'yes'.

Query: Verify if the sentence expresses a "positive" sentiment toward "salad" solely based on the use of the opinion term "decent". Reasoning: The salad is described as okay, not decent, which exaggerates the sentiment. The mismatch in opinion and aspect makes this query invalid. Thus, the output is 'no'. Query: Verify if the sentence expresses a "negative" sentiment toward "dessert options" solely based on the use of the opinion term "limited". Reasoning: The aspect dessert options is described by limited, which suggests a negative sentiment due to lack of variety. The opinion correctly aligns with the aspect, so this query is valid. Thus, the output is 'yes'.

Query: Verify if the sentence expresses a "negative" sentiment toward "Alfredo sauce" solely based on the use of the opinion term "limited". Reasoning: The opinion limited is incorrectly assigned to Alfredo sauce, which was actually described as decent. Since the opinion-aspect match is wrong, this query is invalid. Thus, the output is 'no'.

Query: Verify if the sentence expresses a "neutral" sentiment toward "dessert options" solely based on the use of the opinion term "okay". Reasoning: The opinion okay does not describe dessert options; instead, limited does, which carries a negative sentiment. Since the polarity is misclassified, this query is invalid. Thus, the output is 'no'.

Query: Verify if the sentence expresses a "neutral" sentiment toward "salad" solely based on the use of the opinion term "okay". Reasoning: The aspect salad is described as okay, which implies a neutral sentiment. The polarity is correctly assigned as neutral, making this query valid. Thus, the output is 'yes'.

## A.4 Dataset Statistics

The table [6] presents the dataset statistics as provided by [(Xu et al., 2020)], it includes the statistics of the number of targets with one opinion span and the number of targets with multiple opinion spans, and also shows the number of opinions corresponding with single or multiple target spans respectively.

The statistics related to the number of opinion576terms for each polarity for 14Rest, 14Lap, 15Rest577and 16Rest an be found in table [7], also provided578by [(Xu et al., 2020)].579
