

# First the worst: Finding better gender translations during beam search

Anonymous ACL submission

## Abstract

Generating machine translations via beam search seeks the most likely output under a model. However, beam search has been shown to amplify demographic biases exhibited by a model. We aim to address this, focusing on gender bias resulting from systematic errors in grammatical gender translation. Almost all prior work on this problem adjusts the training data or the model itself. By contrast, our approach changes only the inference procedure.

We explore two techniques: applying constraints during inference to improve gender diversity in n-best lists, and reranking n-best lists using gender features obtained from the source sentence. Combining these methods gives large gains in gender translation accuracy for three language pairs without requiring additional bilingual data or retraining.

## 1 Introduction

Neural language generation models optimized by likelihood have a tendency towards ‘safe’ word choice. This lack of output diversity has been noted in NMT (Vanmassenhove et al., 2019) and throughout NLP (Li et al., 2016; Sultan et al., 2020). Model-generated language may be repetitive or stilted. More insidiously, generating the most likely output based only on corpus statistics can amplify any existing biases in the corpus (Zhao et al., 2017).

Potential harms arise when biases around word choice or grammatical gender inflections reflect demographic or social biases (Sun et al., 2019). The resulting gender mistranslations could involve implicit misgendering of a user or other referent, or perpetuation of social stereotypes about the ‘typical’ gender of a referent in a given context.

Dominant approaches to the problem almost exclusively involve retraining (Vanmassenhove et al., 2018; Escudé Font and Costa-jussà, 2019; Stafanovič et al., 2020) or tuning (Saunders and Byrne, 2020; Basta et al., 2020) on gender-adjusted

data. Such approaches are often computationally expensive and risk introducing new biases (Shah et al., 2020). Instead, this paper seeks to improve translations from existing models. Roberts et al. (2020) have recently highlighted beam search’s tendency to amplify gender bias – we aim to guide it instead towards finding better gender translations.

Our contributions are as follows: we rerank the n-best lists of NMT models exhibiting gender bias, demonstrating that we can extract better gender translations from the *original model*’s beam. We also generate new n-best lists subject to gendered inflection constraints, and show this increases the frequency of correctly gendered entities appearing in n-best lists. We make no changes to the NMT model or training data, and require only monolingual resources for the source and target languages.

### 1.1 Related work

Prior work mitigating gender bias in NLP often involves adjusting training data, directly (Zhao et al., 2018) or via embeddings (Bolukbasi et al., 2016). Our inference-only approach is closer to work on controlling or ‘correcting’ gendered output.

Controlling gender translation generally involves introducing external information into the model. Miculicich Werlen and Popescu-Belis (2017) integrate cross-sentence coreference links into reranking to improve pronoun translation. Vanmassenhove et al. (2018) and Moryossef et al. (2019) incorporate sentence-level gender features into training data and during inference respectively. Token-level source gender tags are used by Stafanovič et al. (2020) and Saunders et al. (2020). As in this prior work, our focus is applying linguistic gender-consistency information, rather than obtaining it.

A separate line of work treats gender-related inconsistencies as a search and correction problem. Roberts et al. (2020) find that beam search amplifies gender bias compared to sampling search. Saunders and Byrne (2020) rescore trans-

lations with a model fine-tuned for additional gender sensitivity, constraining outputs to gendered-reinfections of the original. Related approaches for monolingual tasks reinflect whole-sentence gender (Habash et al., 2019; Alhafni et al., 2020; Sun et al., 2021). An important difference in our work is use of the same model for initial translation and reinfection, reducing computation and complexity.

## 2 Finding consistent gender in the beam

There are two elements to our proposed approach. First, we *produce an n-best list* of translations using our single model per language pair. We use either standard beam search or a two-pass approach where the second pass searches for differently-gendered versions of the highest likelihood initial translation. We then *select a translation* from the list, either by log likelihood or by how far the target language gender features correspond to the source sentence.

### 2.1 Gender-constrained n-best lists

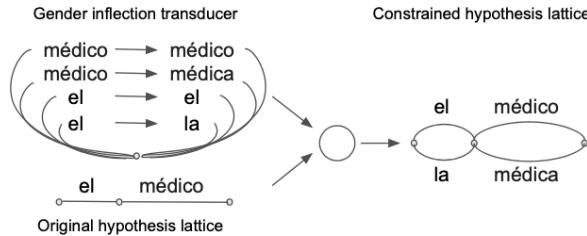

Figure 1: Constraints for a toy initial hypothesis.

We produce n-best lists in two ways. One option is standard beam search. Alternatively, we synthesize n-best lists using the gendered constraint scheme of Saunders and Byrne (2020), illustrated in Figure 1. This involves a second *gender-constrained* beam search pass to reinfect an initial hypothesis, producing a synthesized n-best list containing gendered alternatives of that hypothesis.

The second reinfection pass uses a target language *gender inflection transducer* which defines grammatically gendered reinfections. For example, Spanish definite article *el* could be unchanged or reinjected to *la*, and profession noun *médico* could be reinjected to *médica* (and vice versa). Composing the reinfections with the original hypothesis generates a *constrained hypothesis lattice*.

We can now perform constrained beam search, which can encourage NMT to output specific vocabulary (Stahlberg et al., 2016; Khayrallah et al., 2017). The only difference from standard beam

search is that gender-constrained search only expands translations forming paths in the constrained hypothesis lattice. In the Figure 1 example, beam- $n$  search would produce the  $n$  most likely translations, while the gender-constrained pass would only produce the 4 translations in the lattice.

Importantly, for each language pair we use just one NMT model to produce gendered variations of its *own* hypotheses. Unlike Saunders and Byrne (2020) we do not reinfect translations with a separate gender-sensitive model. This removes the complexity, potential bias amplification and computational load of developing the gender-translation-specific models central to their approach.

While we perform two full inference passes to simplify implementation, further efficiency improvements are possible. For example, the source sentence encoding could be reused for the reinfection pass. In principle, some beam search constraints could be applied in the first inference pass, negating the need for two passes. These potential efficiency gains would not be possible if using a separate NMT model to reinfect the translations.

### 2.2 Reranking gendered translations

---

#### Algorithm 1 Gender-reranking an n-best list

**Input:**  $x$ : Source sentence;  $Y$ : set of translation hypotheses for  $x$ ;  $L$ : Log likelihoods for all  $y \in Y$ ;  $A$ : word alignments between  $x$  and all  $y$

```

 $p, p_g \leftarrow \text{pronoun\_and\_gender}(x)$      $\triangleright$  Or oracle
 $e \leftarrow \text{get\_entity}(x, p)$                    $\triangleright$  Or oracle
for all  $y \in Y$  do
     $y_{score} \leftarrow 0$ 
    for all  $t \in A_y(e)$  do       $\triangleright$  Translated entity
         $t_g \leftarrow \text{get\_gender}(t)$ 
        if  $t_g = p_g$  then
             $y_{score} += 1$ 
        end if
    end for
end for
 $\hat{Y} = \{\text{argmax}_y(y_{score}, y \in Y)\}$ 
 $\hat{y} = \text{argmax}_y(L(y), y \in \hat{Y})$ 
return  $\hat{y}$ 

```

---

We select an output translation from an n-best list in two ways, regardless of whether the list was produced by beam search or the two-pass approach. One option selects the highest-likelihood translation under the NMT model. Alternatively, we rerank for gender consistency with the source

150 sentence. We focus on either *oracle* or *inferred*  
151 entities coreferent with a source pronoun.

152 The *oracle* case occurs in several scenarios. Oracle  
153 entity labels could be provided as for the  
154 WinoMT challenge set (Stanovsky et al., 2019).  
155 They could also be user-defined for known  
156 entities (Vanmassenhove et al., 2018), or if translating  
157 the same sentence with different entity genders to  
158 produce multiple outputs (Moryossef et al., 2019).

159 The *inferred* case determines entities automatically.  
160 In Algorithm 1, `pronoun_and_gender` finds  
161 a source pronoun and its grammatical gender. We  
162 then find coreferent entities using a target lan-  
163 guage coreference resolution tool in `get_entity`. For  
164 brevity Algorithm 1 is written for one entity per  
165 sentence: in practice there is no such limit.

166 For each entity we find the aligned translated  
167 entity, similar to Stafanovičs et al. (2020). We  
168 determine the translated entity’s grammatical gen-  
169 der by target language morphological analysis in  
170 `get_gender`. Finally we rerank, first by source gen-  
171 der agreement, tie-breaking with log likelihood<sup>1</sup>.

### 172 3 Experimental setup

173 We translate English into German, Spanish and  
174 Hebrew using Transformers (Vaswani et al., 2017)  
175 with 30K BPE vocabularies (Sennrich et al., 2016).  
176 We train the en-de model on WMT19 newstask data  
177 including filtered Paracrawl (Barrault et al., 2019),  
178 en-es on UNCorpus data (Ziemski et al., 2016), and  
179 en-he on the IWSLT corpus (Cettolo et al., 2014).  
180 For further training details see Appendix A.

181 Some proposed steps require tools or resources:  
182 1) For gender-constrained search, creating gender  
183 inflection transducers; 2) For inferred-reranking,  
184 finding source gendered entities 3) For all rerank-  
185 ing, finding translated gendered entities; 4) For all  
186 reranking, getting translated entity genders.

187 For 1) we use Spacy (Honnibal and Montani,  
188 2017) and DEMorphy (Altinok, 2018) morpholog-  
189 ical analysis for Spanish and German, and fixed  
190 rules for Hebrew, on large vocabulary lists to pro-  
191 duce gender transducers, directly following Saun-  
192 ders and Byrne (2020)<sup>2</sup>. The highest likelihood  
193 outputs from beam-4 search form the original hy-  
194 pothesis lattices. For 2) we use a RoBERTa model  
195 (Liu et al., 2019) tuned for coreference on Wino-

196 grad challenge data<sup>3</sup>. For 3) we use fast\_align  
197 (Dyer et al., 2013). For 4) we use the same mor-  
198 phological analysis as in 1, now on translated entities.

199 We evaluate gender translation on WinoMT  
200 (Stanovsky et al., 2019), measuring overall accu-  
201 racy and  $\Delta G$  (F1 score difference between mascu-  
202 line and feminine labelled sentences, closer to 0  
203 is better). As WinoMT lacks references we assess  
204 cased BLEU on WMT18 (en-de, 3K sentences),  
205 WMT13 (en-es, 3K sentences) and IWSLT14 (en-  
206 he, 962 sentences) using SacreBLEU (Post, 2018).  
207 For validation during NMT model training we use  
208 test sets from earlier years of the same tasks.

### 209 4 Results and discussion

210 We first discuss the possibilities of oracle-reranking  
211 n-best lists in Table 1, before proceeding to the  
212 more general scenario of inferred-reranking. Com-  
213 paring lines 1 vs 2, gender-constrained beam-4  
214 search scores very closely to standard beam-4  
215 search for all metrics and language pairs if simply  
216 taking the highest likelihood output. For beam-20  
217 (5 vs 6) en-de and en-es, constraints do mitigate  
218 the BLEU degradation common with larger beams  
219 (Stahlberg and Byrne, 2019).

220 In lines 1 vs 3, 5 vs 7, we oracle-rerank beam  
221 search outputs instead of choosing by highest like-  
222 lihood. We see about 10% accuracy improvement  
223 relative to non-reranked beam-4 across languages,  
224 and over 25% relative improvement for beam-20.  
225 Combining oracle-reranking and constraints further  
226 boosts accuracy. This suggests constraints encour-  
227 age presence of better gender translations in n-best  
228 lists, but that reranking is needed to extract them.

229 Using beam-20 significantly improves the per-  
230 formance of reranking. With constraints, beam-20  
231 oracle-reranking gives *absolute* accuracy gains of  
232 about 20% over the highest likelihood beam search  
233 output. However, beam-4 shows most of the im-  
234 provement over that baseline. We find diminishing  
235 returns as beam size increases (Appendix B), sug-  
236 gesting large, expensive beams are not necessary.

237 So far we have shown accuracy improvements  
238 with oracle reranking, indicating that the synthe-  
239 sized n-best lists often contain a gender-accurate  
240 hypothesis. In Table 2, we explore inferred-  
241 reranking using a RoBERTa model, investigating  
242 whether that hypothesis can be found automatically.  
243 We find very little degradation in WinoMT accu-

	S&B + rerank	83.6	73.9	62.9

Table 3: WinoMT accuracy for inferred-reranking the adaptation scheme of [Saunders and Byrne \(2020\)](#).

accuracy when inferring entities compared to the oracle (Table 1). We hypothesise that difficult sentences are hard for both coreference resolution and NMT, so cases where RoBERTa disambiguates wrongly are also mistranslated with oracle information.

We are unable to oracle-rerank the generic test sets, since they have no oracle gender labels. However, we can tag them using RoBERTa for inferred-reranking. In Table 2 we find this has little or no impact on BLEU score, unsurprising for sets not designed to highlight potentially subtle gender translation effects. This suggests positively that our scheme does not impact general translation quality.

So far we have not changed the NMT model at all. In Table 3, for comparison, we investigate the approach of [Saunders and Byrne \(2020\)](#): tuning a model on their dataset of gendered profession sentences, then constrained-rescoring the original model’s hypotheses.<sup>4</sup> We do indeed see strong gender accuracy improvements with their approach, but inferred-reranking the resulting models’ n-best lists further improves scores. We also note that line

4 of Table 2 has higher accuracy than non-reranked beam-20 S&B, without any model fine-tuning.

Finally, we note that our approach can be used for disambiguation in many gender translation scenarios. One benefit beyond the scope of this paper is application to incorporating context: gender information could potentially come from a prior or subsequent sentence, or reflect external user preferences. Another benefit is flexibility to introducing new gendered vocabulary such as neopronouns: if a term can be defined for reranking, it can be searched for in the beam without retraining.

## 5 Conclusions

This paper attempts to improve gender translation without a single change to the NMT model. We demonstrate that gender-constraining the target language during inference can encourage models to produce n-best lists with correct hypotheses. Moreover, we show that simple reranking heuristics can extract more accurate gender translations from the n-best lists using oracle or inferred information.

Unlike other approaches to this problem we do not attempt to counter unidentified and potentially intractable sources of bias in the training data, or produce new models. However, our approach does significantly boost the accuracy of a prior data-centric bias mitigation technique. In general we view our scheme as orthogonal to such approaches: if a model ranks diverse gender translations higher in the beam initially, finding better gender translations during beam search becomes simpler.

<sup>4</sup>Different scores from the original authors may be due to variations in hyperparameters, or WinoMT updates.

## 297 Impact statement<sup>5</sup>

298 Where machine translation is used in people’s lives,  
299 mistranslations have the potential to misrepresent  
300 people. This is the case when personal character-  
301 teristics like social gender conflict with model biases  
302 towards certain forms of grammatical gender. As  
303 mentioned in the introduction, the result can in-  
304 involve implicit misgendering of a user or other hu-  
305 man referent, or perpetuation of social biases about  
306 gender roles as represented in the translation. A  
307 user whose words are translated with gender de-  
308 faults that imply they hold such biased views will  
309 also be misrepresented.

310 We attempt to avoid these failure modes by iden-  
311 tifying translations which are at least consistent  
312 within the translation and with the source sentence.  
313 This is dependent on identifying grammatically  
314 gendered terms in the target language – however,  
315 this element is very flexible and can be updated for  
316 new gendered terminology. We note that models  
317 which do not account for variety in gender expres-  
318 sion such as neopronoun use may not be capable  
319 of generating appropriate gender translations, but  
320 in principle a variety of gender translations could  
321 be extracted from the beam.

322 By avoiding the data augmentation, tuning and  
323 retraining elements in previously proposed ap-  
324 proaches to gender translation, we seek to simplify  
325 the process and remove additional stages during  
326 which bias could be introduced or amplified (Shah  
327 et al., 2020).

328 In terms of compute time and power, we mini-  
329 mize impact by using a single GPU only for train-  
330 ing the initial NMT models exactly once for the  
331 iterations listed in Appendix A. All other experi-  
332 ments involve rescoring those models and run in  
333 parallel on CPUs in under an hour, except the ex-  
334 periments following Saunders and Byrne (2020),  
335 an approach itself involving only minutes of GPU  
336 fine-tuning.

## 585 A Model training details

586 All NMT models are 6-layer Transformers with a  
 587 30K BPE vocabulary, trained using Tensor2Tensor  
 588 with batch size 4K (Vaswani et al., 2018). All data  
 589 except Hebrew is truecased and tokenized using  
 590 (Koehn et al., 2007). The en-de model is trained  
 591 for 300K batches, en-es for 150K batches, and  
 592 en-he for 15K batches, transfer learning from the en-de  
 593 model. We filter the BPE-ized data for maximum  
 594 (80) and minimum (3) length, and length ratio 3.

## 595 B Beam size for constrained reranking

596 In this paper we present results with beam sizes  
 597 4 and 20. Beam-4 search is commonly-used and  
 598 meets a speed-quality trade-off for NMT (see e.g.  
 599 Junczys-Dowmunt et al. (2016)). Beam-20 is still  
 600 practical, but approaches diminishing returns for  
 601 improved quality without search error mitigation  
 602 (Stahlberg and Byrne, 2019). These beam sizes  
 603 therefore illustrate contrasting levels of practical  
 604 reranking. However, it is instructive to consider  
 605 how wide a beam is really needed for improvements  
 606 under gender-constrained reranking.

607 In Figure 2 we report WinoMT accuracy under  
 608 gender-constrained oracle reranking with beam  
 609 width increasing by intervals of 4. For all systems,  
 610 the largest jump in improvement is between beam  
 611 sizes 4 and 8, with diminishing returns after beam-  
 612 12. The en-de curve is relatively shallow, possibly  
 613 due to strong scores before reranking, or even a  
 614 performance ceiling determined by the WinoMT  
 615 framework itself. Curves for en-he and en-es are  
 616 very close, suggesting a similarity between the  
 617 gender distribution in the n-best lists for those models.

## 618 C Constrained vs unconstrained beams

619 We can observe the difference between standard  
 620 and constrained beam search by examining the n-  
 621 best lists. Table 4 (next page) gives 5 examples of 4-  
 622 best lists for WinoMT sentences translated into Ger-  
 623 man. Examples are not cherry-picked but selected  
 624 from throughout WinoMT with a random number  
 625 generator. Lists are ordered by NMT model like-  
 626 lihood and produced with standard unconstrained  
 627 beam search, and with constrained beam search.

628 With standard unconstrained beam search, trans-  
 629 lations vary primarily in words unrelated to the  
 630 entities, such as synonyms or verb tenses. How-  
 631 ever, entity grammatical genders are generally un-  
 632 changed throughout the unconstrained n-best lists,

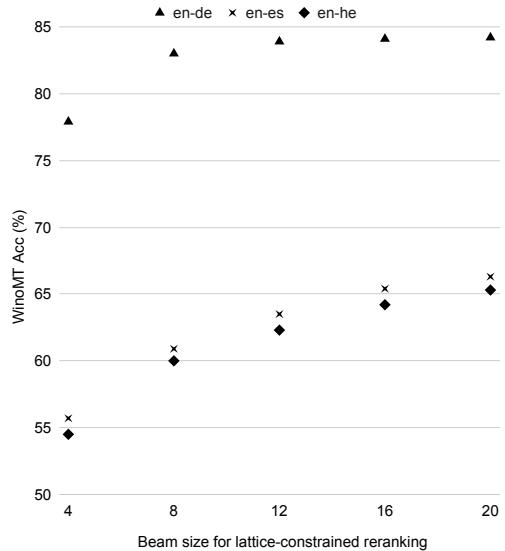

Figure 2: WinoMT accuracy after oracle-reranking gender-constrained n-best lists, varying n.

except for 1 where the secondary entity changes.  
 633 Reranking cannot always find a gender-consistent  
 634 translation in the unconstrained lists, defaulting to  
 635 the 1best for all except 2 (which seems to have a  
 636 poorly aligned hypothesis).

637 By contrast, constrained beam search ensures  
 638 the n-best list contains gendered inflections of the  
 639 initial best-scoring translation. The changes vary  
 640 the grammatical genders of articles and entities,  
 641 resulting in more gender-diverse hypotheses, and  
 642 allowing reranking to find a better translation for 1.

643 We note that in 3, 4 and 5 both the pronoun  
 644 and the default gender convention for unknown  
 645 gender entities are masculine. Reranking is not  
 646 strictly necessary to find a better translation for  
 647 these sentences, since the highest likelihood output  
 648 is gender-consistent. However, we note that some  
 649 outputs with gender constraints do in fact vary the  
 650 gender of the secondary entity – the entity with  
 651 unspecified gender. This illustrates our approach’s  
 652 ability to improve n-best list diversity even when it  
 653 does not necessarily impact translation consistency.

654 We observe occasional grammatical inconsisten-  
 655 cies in n-best hypotheses (e.g. "die Fahrer" in 3).  
 656 When constraining beam search to grammatical  
 657 variations of a sentence with an imperfect NMT  
 658 model, we expect some hypotheses with grammat-  
 659 ical degradation. However, our priority, and the  
 660 purpose of our reranking scheme, is consistency  
 661 with the source in the output translation, not incon-  
 662 sistencies elsewhere in the n-best list.

1. The broker called the client because <u>she</u> had new stocks to recommend.	
Unconstrained	* <i>Der Makler rief den Kunden an, weil sie neue Aktien zu empfehlen hatte.</i> <i>Der Makler rief die Klientin an, weil sie neue Aktien zu empfehlen hatte.</i> <i>Der Makler rief den Klienten an, weil sie neue Aktien zu empfehlen hatte.</i> <i>Der Makler rief den Kunden an, weil er neue Aktien zu empfehlen hatte.</i>
Constrained	<i>Der Makler rief den Kunden an, weil sie neue Aktien zu empfehlen hatte.</i> <i>Der Makler rief den Kunden an, weil er neue Aktien zu empfehlen hatte.</i> * <i>Die Maklerin rief den Kunden an, weil sie neue Aktien zu empfehlen hatte.</i> <i>Der Makler rief die Kunden an, weil sie neue Aktien zu empfehlen hatte.</i>
2. The teacher explained the situation to <u>the chief</u> and felt understood by <u>her</u> .	
Unconstrained	<u>Die Lehrerin</u> erklärte die Situation <i>dem Chef</i> und fühlte sich von <u>ihr</u> verstanden. * <u>Die Lehrerin</u> erklärte <i>dem Obersten</i> die Situation und fühlte sich von <u>ihr</u> verstanden. <u>Die Lehrerin</u> erklärte die Situation <i>dem Obersten</i> und fühlte sich von <u>ihr</u> verstanden. <u>Die Lehrerin</u> erläuterte die Situation <i>dem Obersten</i> und fühlte sich von <u>ihr</u> verstanden.
Constrained	* <u>Die Lehrerin</u> erklärte die Situation <i>dem Chef</i> und fühlte sich von <u>ihr</u> verstanden. <i>Der Lehrer</i> erklärte die Situation <i>dem Chef</i> und fühlte sich von <u>ihr</u> verstanden. <i>Der Lehrer</i> erklärte die Situation <i>dem Chef</i> und fühlte sich von <u>ihm</u> verstanden. <u>Die Lehrerin</u> erklärte die Situation <i>dem Chef</i> und fühlte sich von <u>ihm</u> verstanden.
3. The assistant hired <u>the driver</u> as <u>he</u> offered an excellent service.	
Unconstrained	* <u>Der Assistent</u> stellte <i>den Fahrer</i> ein, da <u>er</u> einen ausgezeichneten Service bot. <i>Der Assistent</i> stellte <i>den Fahrer</i> ein, da <u>er</u> einen exzellenten Service bot. <i>Der Assistent</i> stellte <i>den Fahrer</i> ein, da <u>er</u> einen hervorragenden Service bot. <i>Der Assistent</i> stellte <i>den Fahrer</i> ein, als <u>er</u> einen ausgezeichneten Service bot.
Constrained	* <u>Der Assistent</u> stellte <i>den Fahrer</i> ein, da <u>er</u> einen ausgezeichneten Service bot. <u>Die Assistentin</u> stellte <i>den Fahrer</i> ein, da <u>er</u> einen ausgezeichneten Service bot. <i>Der Assistent</i> stellte <u>die Fahrer</u> ein, da <u>er</u> einen ausgezeichneten Service bot. <i>Der Assistent</i> stellte <i>den Fahrer</i> ein, da <u>er</u> eine ausgezeichnete Service bot.
4. <u>The laborer</u> handed the application to <u>the editor</u> because <u>he</u> wants the job.	
Unconstrained	* <u>Der Arbeiter</u> übergab den Antrag an <i>den Herausgeber</i> , weil <u>er</u> den Job will. <i>Der Arbeiter</i> übergab die Bewerbung an <i>den Herausgeber</i> , weil <u>er</u> die Arbeit will. <i>Der Arbeiter</i> übergab die Bewerbung an <i>den Herausgeber</i> , weil <u>er</u> den Job will. <i>Der Arbeiter</i> überreichte die Bewerbung an <i>den Herausgeber</i> , weil <u>er</u> die Arbeit will.
Constrained	* <u>Der Arbeiter</u> übergab den Antrag an <i>den Herausgeber</i> , weil <u>er</u> den Job will. <i>Der Arbeiter</i> übergab den Antrag an <i>den Herausgeber</i> , weil <u>er</u> diesen Job will. <i>Der Arbeiter</i> übergab den Antrag an <i>den Herausgeber</i> , weil <u>er</u> die Job will. <i>Der Arbeiter</i> übergab die Antrag an <i>den Herausgeber</i> , weil <u>er</u> die Job will.
5. <u>The developer</u> was unable to communicate with <u>the writer</u> because <u>he</u> only understands the code.	
Unconstrained	* <u>Der Entwickler</u> konnte nicht mit <i>dem Schriftsteller</i> kommunizieren, weil <u>er</u> nur den Code versteht. <i>Der Entwickler</i> konnte nicht mit <i>dem Autor</i> kommunizieren, weil <u>er</u> nur den Code versteht. <i>Der Entwickler</i> war nicht in der Lage, mit <i>dem Schriftsteller</i> zu kommunizieren, weil <u>er</u> nur den Code versteht. <i>Der Entwickler</i> war nicht in der Lage, mit <i>dem Autor</i> zu kommunizieren, weil <u>er</u> nur den Code versteht.
Constrained	* <u>Der Entwickler</u> konnte nicht mit <i>dem Schriftsteller</i> kommunizieren, weil <u>er</u> nur den Code versteht. <i>Der Entwickler</i> konnte nicht mit <i>der Schriftstellerin</i> kommunizieren, weil <u>er</u> nur den Code versteht. <i>Der Entwickler</i> konnte nicht mit <i>dem Schriftsteller</i> kommunizieren, weil <u>er</u> nur die Code versteht. <i>Der Entwickler</i> konnte nicht mit <i>dem Schriftsteller</i> kommunizieren, weil <u>er</u> nur diesen Code versteht.

Table 4: English-German 4-best lists for 5 randomly-selected Winomt sentences, translated with normal beam search and gender-constrained beam search. Grammatically feminine human entities are underlined. Grammatically masculine human entities are *emphasised*. Lists are ordered by NMT model likelihood (first is 1best) - lines marked with \* are those selected under oracle-reranking.

- 1: Constrained reranking finds a better gender translation that is not present in the unconstrained beam.
- 2: A better gendered translation is not found in either width-4 beam. Constraints still maintain semantic meaning throughout the beam while allowing syntactic variation, including a differently gendered secondary entity.
- 3, 4, 5: The highest likelihood output is acceptable. For 3 and 5 constraining the n-best list results in more gender variation.
