

# HOMOMORPHISM EXPRESSIVITY OF SPECTRAL INVARIANT GRAPH NEURAL NETWORKS

**Anonymous authors**

Paper under double-blind review

## ABSTRACT

Graph spectra are an important class of structural features on graphs that have shown promising results in enhancing Graph Neural Networks (GNNs). Despite their widespread practical use, the theoretical understanding of the power of spectral invariants — particularly their contribution to GNNs — remains incomplete. In this paper, we address this fundamental question through the lens of homomorphism expressivity, providing a comprehensive and quantitative analysis of the expressive power of spectral invariants. Specifically, we prove that spectral invariant GNNs can homomorphism-count exactly a class of specific tree-like graphs which we refer to as *parallel trees*. We highlight the significance of this result in various contexts, including establishing a quantitative expressiveness hierarchy across different architectural variants, offering insights into the impact of GNN depth, and understanding the subgraph counting capabilities of spectral invariant GNNs. In particular, our results significantly extend Arvind et al. (2024) and settle their open questions. Finally, we generalize our analysis to higher-order GNNs and answer an open question raised by Zhang et al. (2024b).

## 1 INTRODUCTION

The graph spectrum, defined as the eigenvalues of a graph matrix, is an important class of graph invariants. It encapsulates rich graph structural information including the graph connectivity, bipartiteness, node clustering patterns, diameter, and more (Brouwer & Haemers, 2011). Besides eigenvalues, generalized spectral information may also include projection matrices, which further encodes node relations such as distances and random walk properties, enabling the definition of more fine-grained graph invariants (Fürer, 2010). These spectral invariants possesses strong *expressive power*. For example, a well-known conjecture raised by Van Dam & Haemers (2003); Haemers & Spence (2004) claimed that almost all graphs can be uniquely determined by their spectra up to isomorphism. The rare exceptions, known as cospectral graphs, tend to be highly similar in their structure and continue to be an active area of research in graph theory (Lorenzen, 2022).

In the machine learning community, spectral invariants have recently gained increasing popularity in designing Graph Neural Networks (GNNs) (Bruna et al., 2013; Defferrard et al., 2016; Lim et al., 2023; Huang et al., 2024; Feldman et al., 2023; Zhang et al., 2024b; Black et al., 2024; Katsoulis & Ribeiro), owing to several reasons. From a practical perspective, graph spectra have been shown to be closely related to certain practical applications such as molecular property prediction (Bonchev, 2018). Moreover, a recent line of works (Xu et al., 2019; Morris et al., 2019; Li et al., 2020; Chen et al., 2020; Zhang et al., 2023b) has pointed out that the expressive power of classic message-passing neural networks (MPNNs) are inherently limited, and cannot encode important graph structure like connectivity or distance. Incorporating spectral invariants into the design of MPNNs can naturally alleviate the limitations.

Therefore, from both theoretical and practical perspectives, it is beneficial to give a systematic understanding of the power of spectral invariants and their corresponding GNNs. The earliest study in this area may be traced back to Fürer (2010), who first linked the power of several spectral invariants to the classic Weisfeiler-Lehman test (Weisfeiler & Lehman, 1968) by proving that these invariants are upper bounded by 2-FWL. More recently, Rattan & Seppelt (2023) further revealed a strict expressivity gap between Fürer’s spectral invariants and 2-FWL. Zhang et al. (2024b) and Arvind et al. (2024) analyzed *refinement-based* spectral invariants, which offer insights into the power of real GNN architectures. Yet, all of these works study expressiveness through the lens of Weisfeiler-Lehman tests, which has inherent limitations. So far, there remains a lack of *comprehensive* understanding of the *practical* power of spectral invariants and their corresponding GNN architectures.

**Current work.** In this paper, we investigate the aforementioned questions via a novel perspective called *graph homomorphism*. Specifically, Zhang et al. (2024a) recently proposed homomorphism expressivity as a quantitative framework to better understand the expressive power of various GNN architectures. As homomorphism expressivity is a fine-grained and practical measure, it naturally addresses several limitations of the WL test. However, extending this framework to other architectures, such as spectral invariant GNNs, poses significant challenges. In fact, whether homomorphism expressivity exists for a given architecture remains an open research direction (see Zhang et al. (2024a)). In our context, this problem becomes even challenging since homomorphism and spectral invariants correspond to two orthogonal branches in graph theory. Here, we provide affirmative answers to all these questions by formally proving that the homomorphism expressivity for spectral invariant GNNs exists and can be elegantly characterized as a special class of *parallel trees* (Theorem 3.3). This offers deep insights into a series of previous studies, extending their results and answering several open questions. We summarize our results below:

- **Separation power of spectral invariants/GNNs.** We offer a new proof that projection-based spectral invariants and corresponding GNNs are strictly bounded by 2-FWL (Corollary 3.4). Moreover, we establish a *quantitative hierarchy* among raw spectra information, projection, refinement-based spectral invariant, and various combinatorial variants of WL tests (see Figure 4). This (i) recovers and extends results in Rattan & Seppelt (2023), and (ii) provides clear insights into the hierarchy established in Zhang et al. (2024b).
- **The power of refinement.** We offer a systematic understanding of the role of refinement in spectral invariant GNNs. We show increasing the number of iterations always leads to a strict improvement in expressive power (Corollary 3.11), thus settling a key open question raised in Arvind et al. (2024). Moreover, our counterexamples establish a tight lower bound on the number of iterations required to achieve maximal expressivity, which is in the same order of graph size. This advances a line of research regarding iteration numbers in WL tests (Fürer, 2001; Kiefer & Schweitzer, 2016; Lichter et al., 2019).
- **Substructure counting power of spectral invariants/GNNs.** On the practical side, we precisely characterize the power of spectral invariants/GNNs in counting certain subgraphs as well as the required iterations. For example, they can count all cycles within 7 vertices, while using 1 iteration already suffices to count all cycles within 6 vertices (Corollary 3.15).

Empirically, a set of experiments on both synthetic and real-world tasks validate our theoretical results, showing that the homomorphism expressivity of spectral invariant GNNs well reflects their performance in down-stream tasks.

## 2 PRELIMINARIES

**Notations.** We use  $\{ \}$  and  $\{ \{ \}$  to denote sets and multisets, respectively. The cardinality of a given (multi)set  $S$  is denoted as  $|S|$ . In this paper, we consider finite, undirected, simple graphs with no self-loops or repeated edges, and without loss of generality we only consider connected graphs. Let  $G = (V_G, E_G)$  be a graph with vertex set  $V_G$  and edge set  $E_G$ , where each edge in  $E_G$  is a set  $\{u, v\} \subset V_G$  of cardinality two. The *neighbors* of vertex  $u$  is denoted as  $N_G(u) := \{v \in V_G | \{u, v\} \in E_G\}$ . A *walk* of length  $k$  is a sequence of vertices  $u_0, \dots, u_k \in V_G$  such that  $\{u_{i-1}, u_i\} \in E_G$  for all  $i \in [k]$ . It is further called a *path* if  $u_i \neq u_j$  for all  $i < j$ , and it is called a *cycle* if  $u_0, \dots, u_{k-1}$  is a path and  $u_0 = u_k$ . The shortest path distance between two nodes  $u, v \in V_G$ , denoted as  $\text{dis}_G(u, v)$ , is the minimum length of walk from  $u$  to  $v$ . A graph  $F = (V_F, E_F)$  is a *subgraph* of  $G$  if  $V_F \subset V_G$  and  $E_F \subset E_G$ . We use  $P_n$  (resp.  $C_n$ ) to denote a graph corresponding to a path (resp. cycle) of  $n$  vertices. A graph is called a *tree* if it is connected and contains no cycle as a subgraph. We denote by  $T^r$  the rooted tree  $T$  with root  $r$ . The depth of a rooted tree  $T^r$  is defined as  $\text{dep}(T^r) = \max_{u \in V_T} \text{dis}_T(r, u)$ .

### 2.1 SPECTRAL INVARIANT GNNs

Let  $G$  be a graph of  $n$  vertices where  $V_G = [n]$ , and denote by  $\mathbf{A} \in \{0, 1\}^{n \times n}$  the adjacency matrix of  $G$ . The *spectrum* of  $G$  is defined as the multiset of all eigenvalues of  $\mathbf{A}$ . In addition to eigenvalues, eigenspaces also provide important spectral information. Formally, the eigenspace associated with some eigenvalue  $\lambda$  can be characterized by its projection matrix  $\mathbf{P}_\lambda$ . It follows that

there exist a unique set of orthogonal projection matrices  $\{\mathbf{P}_\lambda\}_{\lambda \in \Lambda}$ , where  $\Lambda$  is the set of all distinct eigenvalues of  $\mathbf{A}$ , such that  $\mathbf{A} = \sum_{\lambda \in \Lambda} \lambda \mathbf{P}_\lambda$ , and the following conditions hold:  $\sum_{\lambda} \mathbf{P}_\lambda = \mathbf{I}$ ,  $\mathbf{P}_\lambda \mathbf{P}_{\lambda'} = 0$  for  $\lambda \neq \lambda'$ , and  $\mathbf{A} \mathbf{P}_\lambda = \mathbf{P}_\lambda \mathbf{A}$  for all  $\lambda \in \Lambda$ . Combining the projection matrices with the associated eigenvalues naturally define an invariant between node pairs, which we denote by  $\mathcal{P}$ :

$$\mathcal{P}(u, v) := \{(\lambda, \mathbf{P}_\lambda(u, v)) \mid \lambda \in \Lambda\} \quad \text{for } u, v \in V_G.$$

Then, one can define the so-called ‘‘spectral invariant’’ of a graph as follows. Consider the following color refinement process by treating  $\mathcal{P}(u, v)$  as the edge feature between vertices  $u$  and  $v$ :

$$\chi_G^{\text{Spec},(d+1)}(u) = \text{hash} \left( \chi_G^{\text{Spec},(d)}(u), \{(\chi_G^{\text{Spec},(d)}(v), \mathcal{P}(u, v)) \mid v \in V_G\} \right) \quad \text{for } u \in V_G, d \in N_+,$$

where all colors  $\chi_G^{\text{Spec},(0)}(u)$  ( $u \in V_G$ ) are constant in initialization, and hash is a perfect hash function. For each iteration  $d$ , the mapping  $\chi_G^{\text{Spec},(d)}$  induces an equivalence relation over vertex set  $V_G$ , and the relation gets *refined* with the increase of  $d$ . Therefore, with a sufficiently large number of iterations  $d \leq |V_G|$ , the relations get *stable*. The spectral invariant  $\chi_G^{\text{Spec},(\infty)}(G)$  is then defined to be the multiset of stable node colors. We can similarly define  $\chi_G^{\text{Spec},(d)}(G)$  to be the multiset of node colors after  $d$  iterations (Arvind et al., 2024). We remark that  $\chi_G^{\text{Spec},(1)}(G)$  is exactly the Furer’s (weak) spectral invariant proposed in Furer (2010).

Owing to the relation between GNNs and color refinement algorithms, one can easily transform the above refinement process into a GNN architecture by replacing hash function with a continuous, non-linear, parameterized function, while maintaining the same expressive power (Xu et al., 2019; Morris et al., 2019). We call the resulting architecture Spectral Invariant GNNs, following Zhang et al. (2024b). Without ambiguity, we may also refer to  $\chi_G^{\text{Spec},(d)}(G)$  as the graph representation computed by a  $d$ -layer spectral invariant GNN.

## 2.2 HOMOMORPHISM EXPRESSIVITY

Given two graphs  $F$  and  $G$ , a homomorphism from  $F$  to  $G$  is a mapping  $f : V_F \rightarrow V_G$  that preserves edge relations, i.e.,  $\{f(u), f(v)\} \in E_G$  for all  $\{u, v\} \in E_F$ . We denote by  $\text{Hom}(F, G)$  the set of all homomorphisms from  $F$  to  $G$  and define  $\text{hom}(F, G) = |\text{Hom}(F, G)|$ , which counts the number of homomorphisms. If  $f$  is further surjective on both vertices and edges of  $G$ , we call  $G$  a *homomorphic image* of  $F$ . A mapping  $f : V_F \rightarrow V_G$  is called an isomorphism if  $f$  is a bijection and both  $f$  and its inverse  $f^{-1}$  are homomorphisms. We denote by  $\text{sub}(F, G)$  the number of subgraphs of  $G$  that is isomorphic to  $F$ .

In Zhang et al. (2024a), the authors introduced the concept the homomorphism expressivity to quantify the expressive power of a color refinement algorithm (or GNN). It is formally defined as follows:

**Definition 2.1.** Let  $M$  be a color refinement algorithm (or GNN) that outputs a graph invariant  $\chi_G^M(G)$  given graph  $G$ . The homomorphism expressivity of  $M$ , denoted by  $\mathcal{F}^M$ , is a family of connected graphs<sup>1</sup> satisfying the following conditions:

- For any two graphs  $G, H$ ,  $\chi_G^M(G) = \chi_H^M(H)$  iff  $\text{hom}(F, G) = \text{hom}(F, H)$  for all  $F \in \mathcal{F}^M$ ;
- $\mathcal{F}^M$  is maximal, i.e., for any connected graph  $F \notin \mathcal{F}^M$ , there exists a pair of graphs  $G, H$  such that  $\chi_G^M(G) = \chi_H^M(H)$  and  $\text{hom}(F, G) \neq \text{hom}(F, H)$ .

By characterizing the set  $\mathcal{F}^M$  for different GNN models  $M$ , one can quantitatively understand the expressivity gap between two models by simply computing their set inclusion relation and set difference. Zhang et al. (2024a) examines several representative GNNs under this framework, including the standard MPNNs and Folklore GNNs (Maron et al., 2019; Azizian & Lelarge, 2021), and recent architectures such as Subgraph GNN (Bevilacqua et al., 2022; Qian et al., 2022; Cotta et al., 2021) and Local GNN (Morris et al., 2020; Zhang et al., 2023a). However, one implicit challenge not reflected in Definition 2.1(a) is that the set  $\mathcal{F}^M$  may not even exist for a general GNN  $M$ . Proving the existence corresponds to an involved research topic known as homomorphism distinguishing closedness (Roberson, 2022; Seppelt, 2024; Neuen, 2023) and is highly non-trivial. In the next section, we will give affirmative results showing that the homomorphism expressivity of spectral invariant GNNs does exist and give an elegant description of the graph family.

<sup>1</sup>For simplicity, we focus on *connected* graphs in this paper. The results can be easily generalized to disconnected graphs following Seppelt (2024).

(a) A parallel edge with endpoints  $(u, v)$  (b) An example of parallel tree and its tree skeleton

Figure 1: Illustration of a parallel edge with endpoints  $(u, v)$  in (a) and a parallel tree with its skeleton on the right in (b).

### 3 HOMOMORPHISM EXPRESSIVITY OF SPECTRAL INVARIANT GNNs

In this section, we investigate the homomorphism expressivity of spectral invariants and the corresponding GNNs. We will provide a complete characterization of the set  $\mathcal{F}^{\text{Spec},(d)}$  for arbitrary model depth  $d \in \mathbb{N} \cup \{\infty\}$ . This allows us to analyze spectral invariants in a novel perspective, significantly extending prior research and resolving previously unanswered questions.

#### 3.1 MAIN RESULTS

Our idea is motivated by the previous finding that the homomorphism of MPNN is exactly the family of all trees (Zhang et al., 2024a). Note that in the definition of spectral invariant GNN, if one replaces  $\mathcal{P}(u, v)$  by the standard adjacency  $\mathbf{A}_{uv}$ , the resulting architecture is just an MPNN. Such a relationship perhaps implies that the homomorphism expressivity of spectral invariant GNNs also comprises “tree-like” graphs. We will show this is indeed true. To present our results, let us define a special class of graphs, referred to as *parallel trees*:

**Definition 3.1 (Parallel Edge).** A graph  $G$  is called a *parallel edge* if there exist two different vertices  $u, v \in V_G$  such that the edge set  $E_G$  can be partitioned into a sequence of simple paths  $P_1, \dots, P_m$ , where all paths share endpoints  $(u, v)$ . We refer to  $(u, v)$  as the endpoints of  $G$ .

**Definition 3.2 (Parallel Tree).** A graph  $F$  is called a *parallel tree* if there exists a tree  $T$  such that  $F$  can be obtained from  $T$  by replacing each edge  $(u, v) \in E_T$  with a parallel edge that has endpoints  $(u, v)$ . We refer to  $T$  as the *parallel tree skeleton* of the graph  $F$ . Given a parallel tree  $F$ , the *parallel tree depth* of  $F$  is defined as the minimum depth of any parallel tree skeleton of  $F$ .

We give an illustration of parallel edge and parallel tree in Figure 1. With the above definitions, we are ready to state our main theorem:

**Theorem 3.3.** For any  $d \in \mathbb{N}$ , the homomorphism expressivity of spectral invariant GNNs with  $d$  iterations exists and can be characterized as follows:

$$\mathcal{F}^{\text{Spec},(d)} = \{F \mid F \text{ has parallel tree depth at most } d\}.$$

Specifically, the following properties hold:

- Given any graphs  $G$  and  $H$ ,  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$  if and only if, for all connected graphs  $F$  with parallel tree depth at most  $d$ ,  $\text{hom}(F, G) = \text{hom}(F, H)$ .
- $\mathcal{F}^{\text{Spec},(d)}$  is maximal; that is, for any connected graph  $F \notin \mathcal{F}^{\text{Spec},(d)}$ , there exist graphs  $G$  and  $H$  such that  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$  and  $\text{hom}(F, G) \neq \text{hom}(F, H)$ .

We will present a concise proof sketch of Theorem 3.3 in Section 3.3. Next, in Section 3.2, we will discuss the significance of this result, including how it extends previous findings and addresses open problems identified in earlier studies.

#### 3.2 IMPLICATIONS

Our theory has a wide range of applications, which will be separately discussed in detail below.

##### 3.2.1 COMPARISON WITH 2-FWL

Firstly, we compare the expressive power of spectral invariant GNNs with the expressive power of the standard Weisfeiler-Lehman (WL) test. It immediately follows that the expressive power of spectral invariant GNNs strictly lies between the expressive power of 1-WL and 2-FWL test.

**Corollary 3.4.** *The expressive power of spectral invariant GNNs is strictly stronger than 1-WL and strictly weaker than 2-FWL.*

*Proof.* According to Zhang et al. (2024a), the homomorphism expressivity of 2-FWL encompasses the set of all graphs with treewidth at most 2. A classical result in graph theory states that any subgraph of any series-parallel graph has treewidth at most 2 (Diestel, 2017). Since any parallel tree is clearly a subgraph of some series-parallel graph, its treewidth is at most 2. It follows that the homomorphism expressivity of parallel trees is contained within that of the 2-FWL. To show the gap, we give a counterexample graph in Figure 2. This implies that the expressive power of spectral invariant GNNs is strictly weaker than that of the 2-FWL. The proof for the case of 1-WL is similar and we omit it for clarity.  $\square$

Figure 2: A counterexample graph in  $\mathcal{F}^{2\text{-FWL}} \setminus \mathcal{F}^{\text{Spec},(\infty)}$ .  $\square$

### 3.2.2 HIERARCHY

Theorem 3.3 not only provides insights into the relationship between the expressive power of spectral invariant GNNs and 2-FWL, but also allows for a comparison with a wide range of graph invariants and the corresponding GNNs. Specifically, similar to the analysis in Corollary 3.4, for any GNN models  $A$  and  $B$  such that their homomorphism expressivity exists, if  $\mathcal{F}^A \subsetneq \mathcal{F}^B$ , then  $A$  is strictly weaker than  $B$ . We now use this property to establish a comprehensive hierarchy by linking spectral invariant GNNs to other fundamental graph invariants and GNNs.

**Corollary 3.5.** *Spectral invariant GNN with 1 iteration is strictly weaker than subgraph GNN (also referred to as (1, 1)-WL in Rattan & Seppelt (2023)).*

*Proof.* According to Zhang et al. (2024a), the homomorphism expressivity of subgraph GNNs contains all graphs that become a forest upon the deletion of a specific vertex. On the other hand, Theorem 3.3 states that the homomorphism expressivity of spectral invariant GNNs with one iteration contains all parallel trees of depth 1. Since any parallel tree of depth 1 becomes a forest when deleting the root vertex, we have proved that  $\mathcal{F}^{\text{Spec},(1)}$  is a subset of that of subgraph GNNs. Finally, one can easily construct a counterexample graph to prove the strict separation.  $\square$

**Remark 3.6.** Our result recovers and strengthens the main result in Rattan & Seppelt (2023), which only studied spectral invariants with 1 iteration (Fürer’s weak spectral invariant). We will next show this result actually does *not* hold in case of more than 1 iterations.

**Corollary 3.7.** *Spectral invariant GNNs with 2 iterations are incomparable to subgraph GNNs.*

We provide a counterexample in Figure 3. Nevertheless, we can still bound the expressive power of spectral invariant GNNs with multiple iterations to that of Local 2-GNN, as stated in the following:

**Corollary 3.8.** *For any  $d \in \mathbb{N}_+ \cup \{\infty\}$ , spectral invariant GNNs with  $d$  iterations are strictly weaker than Local 2-GNN (Morris et al., 2020; Zhang et al., 2024a).*

*Proof.* According to Zhang et al. (2024a), the homomorphism expressivity of Local 2-GNNs contains all graphs that admit a strong nested ear decomposition. Since any parallel edge can be partitioned into ears with the same endpoints, one can easily construct a nested ear decomposition for any parallel tree. This shows  $\mathcal{F}^{\text{Spec},(d)}$  is a subset of that of Local 2-GNN. The expressivity gap can be seen using the same counterexample graph in Figure 2.  $\square$

**Remark 3.9.** Corollaries 3.7 and 3.8 significantly extend the findings of Arvind et al. (2024, Theorem 17) and provide additional insights into Zhang et al. (2024b, Theorem 4.3).

**The power of projection.** We next conduct a fine-grained analysis by separating eigenvalues and projections to better understand their individual contributions to enhancing the expressive power of GNN models. We first prove the following theorem:

**Theorem 3.10.** *The homomorphism expressivity of graph spectra is the set of all cycles  $C_n$  ( $n \geq 3$ ) plus paths  $P_1$  and  $P_2$ , i.e.,  $\{C_n | n \geq 3\} \cup \{P_1, P_2\}$ .*

Figure 3: Counterexample for Corollary 3.7 and Corollary 3.11

The proof of Theorem 3.10 is provided in Appendix C, which has the same structure as that of Theorem 3.3. Previously, Van Dam & Haemers (2003); Dell et al. (2018) have proved that the spectra of two graphs  $G$  and  $H$  are identical if and only if for every cycle  $F$ ,  $\text{hom}(F, G) = \text{hom}(F, H)$ . We extend their result by further proving the maximal property (Definition 2.1(b)), which only adds two trivial graphs  $P_1$  and  $P_2$  to the homomorphism expressivity. From this result, one can easily see that using eigenvalues alone can already improve the expressive power of an MPNN since the homomorphism expressivity of MPNN contains only trees (but not cycles).

To understand the role of projection, one can compare the set  $\{C_n | n \geq 3\} \cup \{P_1, P_2\}$  with  $\mathcal{F}^{\text{Spec}, (1)}$  (the homomorphism expressivity of Fürer’s spectral invariant). Clearly, the set of all parallel trees of depth 1 is strictly larger than  $\{C_n | n \geq 3\} \cup \{P_1, P_2\}$ , confirming that adding projection information significantly enhances the expressive power beyond graph spectra.

**The power of refinement.** We finally investigate the power of iterations  $d$  (or number of GNN layers) in enhancing the model’s expressive power. We have the following result:

**Corollary 3.11.** *For any  $d \in \mathbb{N}$ , spectral invariant GNNs with  $d + 1$  iterations are strictly more powerful than spectral invariant GNNs with  $d$  iterations.*

*Proof.* For any  $k \in \mathbb{N}$ , we can construct a counterexample formed by replacing each edge in a path  $P_{2k+1}$  with a parallel edge. We illustrate the construction in Figure 3(b). One can easily see that the resulting graph is in  $\mathcal{F}^{\text{Spec}, (k+1)}$  but not  $\mathcal{F}^{\text{Spec}, (k)}$ .  $\square$

**Remark 3.12.** Corollary 3.11 addresses the key open question posed in Arvind et al. (2024), who conjectured that spectral invariant GNNs converge within *constant* iterations. Specifically, the authors questioned whether, for  $d \geq 4$ , spectral invariant GNNs with  $d + 1$  iterations are as powerful as those with  $d$  iterations. We disproved this conjecture by providing a family of example graphs that cannot be distinguished in  $d$  iterations but can be distinguished in  $d + 1$  iterations.

Our counterexamples further leads to the following result:

**Corollary 3.13.** *For any  $d \in \mathbb{N}_+$ , There exist two graphs with  $\mathcal{O}(d)$  vertices such that spectral invariant GNNs require at least  $d$  iterations to distinguish between them.*

Corollary 3.13 establishes a tight bound on the number of layers needed for spectral invariant GNNs to reach maximal expressivity, showing that it scales with the order of graph size. This advances an important research topic that aims to study the relation between expressiveness and iteration number of color refinement algorithms (Fürer, 2001; Kiefer & Schweitzer, 2016; Lichter et al., 2019).

To summarize all the above results, we illustrate the hierarchy established for spectral invariant GNNs and other mainstream GNNs in Figure 4.

### 3.2.3 SUBGRAPH COUNT

In fact, our results can go beyond the WL framework and reveal the expressive power of spectral invariant GNNs in a more practical perspective. As an example, we will show below how Theorem 3.3 can be used to understand the subgraph counting capabilities of spectral invariant GNNs. Given any graph  $F$ , we say a GNN model  $M$  can subgraph-count substructure  $F$  if for any graphs  $G$  and  $H$ , the condition  $\chi_G^M(G) = \chi_H^M(H)$  implies  $\text{sub}(F, G) = \text{sub}(F, H)$ . Denote by  $\text{Spasm}(F)$  the set of all homomorphic images of  $F$ . Previous results have proved that, if the homomorphism expressivity  $\mathcal{F}^M$  exists for model  $M$ , then  $M$  can subgraph-count  $F$  if and only if  $\text{Spasm}(F) \subset \mathcal{F}^M$  (Seppelt, 2023; Zhang et al., 2024a). This allows us to precisely analyze which substructure can be subgraph-counted by spectral invariant GNNs.

**Corollary 3.14.** *Spectral invariant GNN can count cycles and paths with up to 7 vertices.*

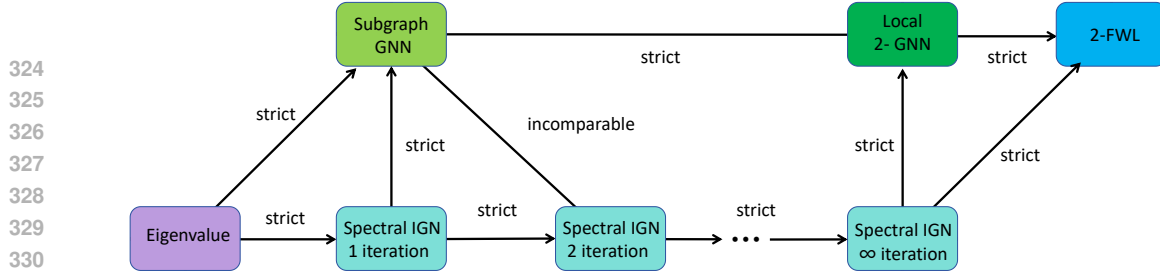

Figure 4: Hierarchy of spectral invariant GNN (abbreviated as Spectral IGN) and other mainstream GNNs. Each arrow points to the strictly stronger architecture.

*Proof.* For cycles or paths with at most 7 vertices, one can check by enumeration that their homomorphic images are all parallel trees. For cycles or paths with at least 8 vertices, the 4-clique is a valid homomorphic image but is not a parallel tree.  $\square$

We can further strengthen the above results by studying the number of iterations needed to count substructures. We have the following results:

**Corollary 3.15.** *The following holds:*

1. *Spectral invariant GNNs can subgraph-count all cycles up to 7 vertices within 2 iterations.*
2. *The above upper bound is tight: spectral invariant GNNs with only 1 iteration (i.e., Fürer’s weak spectral invariant) cannot subgraph-count 7-cycle.*
3. *Spectral invariant GNNs with 1 iteration suffice to subgraph-count all cycles up to 6 vertices.*

**Remark 3.16.** The subgraph counting power of spectral invariant has long been studied in the literature. Cvetkovic et al. (1997) proved that the graph angles (which can be determined by projection) can subgraph-count all cycles of length no more than 5. In comparison, our results significantly extend their findings, which even match the cycle counting power of 2-FWL (Arvind et al., 2020). Moreover, we show that Fürer’s weak spectral invariant can already count 6-cycles, thus extending the work of Fürer (2017).

### 3.3 PROOF SKETCH

In this section, we provide a proof sketch of Theorem 3.3, with the complete proof presented in the Appendix. We begin by demonstrating that the information encoded by spectral invariants is closely related to encoding *walk information* in the aggregation process of GNNs. This corresponds to the following lemma (proved in Appendix B.2):

**Lemma 3.17. (Equivalence of encoding walk and encoding spectral information)** *Let  $G = (V_G, E_G)$  be a graph, with its adjacency matrix denoted by  $A$ . For vertices  $x, y \in V_G$ , define  $\omega_G^k(x, y) = A_{x,y}^k$  for all  $k \in \{0, 1, 2, \dots, |V_G|\}$ , which represents the number of  $k$ -walks from vertex  $x$  to vertex  $y$ . Define the tuple  $\omega_G^*(x, y) = (\omega_G^0(x, y), \omega_G^1(x, y), \dots, \omega_G^{n-1}(x, y))$ , where  $n = |V_G|$ . Define the walk-encoding GNN with the following update rule:*

$$\chi_G^{\text{Walk},(d+1)}(x) = \text{hash}(\chi_G^{\text{Walk},(d)}(x), \{(\omega_G^*(x, y), \chi_G^{\text{Walk},(d)}(y)) \mid y \in V_G\}).$$

*The walk-encoding GNN outputs a representation  $\chi_G^{\text{Walk},(d)}(G) = \{\{\chi_G^{\text{Walk},(d)}(u) \mid u \in V_G\}\}$ . For any graphs  $G, H$ , we have  $\chi_G^{\text{Walk},(d)}(G) = \chi_H^{\text{Walk},(d)}(H)$  if and only if  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$ .*

Our next step aims to prove that for graphs  $G$  and  $H$ ,  $\chi_G^{\text{Walk},(d)}(G) = \chi_H^{\text{Walk},(d)}(H)$  iff, for all graphs  $F$  with parallel tree depth at most  $d$ ,  $\text{hom}(F, G) = \text{hom}(F, H)$ . This will yield the first property outlined in Theorem 3.3. The proof has a similar structure to that in Zhang et al. (2024a), which is based on the tools of tree-decomposed graphs and algebraic graph theory (see Theorems B.14 and B.20 and Lemma B.17). This part corresponds to Appendix B.3.

Now, it remains to prove that the set  $\mathcal{F}^{\text{Spec},(d)}$  is maximal (the second property in Theorem 3.3). To achieve this, we leverage the technique called pebble game (Cai et al., 1992), which was originally used to construct counterexample graphs that cannot be distinguished by the  $k$ -FWL test. We extend the framework and define the pebble game for spectral invariant GNNs as follows:

**Definition 3.18. (Pebble game for spectral invariant GNNs)** The pebble game is conducted on two graphs  $G = (V_G, E_G)$  and  $H = (V_H, E_H)$ . Without loss of generality, we assume  $V_G = V_H$ . Initially, each graph is equipped with two distinct pebbles denoted as  $u$  and  $v$ , which start outside the graphs. The game involves two players: the *spoiler* and the *duplicator*. The game process is described as follows:

- *Initialization:* The spoiler first selects a non-empty subset  $V^S$  from either  $V_G$  or  $V_H$ , and the duplicator responds with a subset  $V^D$  from the other graph, ensuring that  $|V^D| = |V^S|$ . Then, the spoiler places the pebble  $u$  on some vertex in  $V^D$ , and the duplicator places the corresponding pebble  $u$  on some vertex in  $V^S$ . Similarly, the spoiler and duplicator repeat the process to place two pebbles  $v$ . After the initialization, all pebbles will lie on the two graphs.
- *Main Process:* The game iteratively repeats the following steps, where in each iteration the spoiler may choose freely between the following two actions:
  1. Action 1 (moving pebble  $v$ ). The spoiler first selects a non-empty subset  $V^S$  from either  $V_G$  or  $V_H$ , and the duplicator responds with a subset  $V^D$  from the other graph, ensuring that  $|V^D| = |V^S|$ . The spoiler then moves pebble  $v$  to some vertex in  $V^D$ , and the duplicator moves the corresponding pebble  $v$  to some vertex in  $V^S$ .
  2. Action 2 (moving pebble  $u$ ). This action is similar to the above one except that both players move pebble  $u$  instead of pebble  $v$ .
- *Termination:* The spoiler wins if, after a certain number of rounds,  $\omega_G^*(u, v)$  for graph  $G$  differs from  $\omega_H^*(u, v)$  for graph  $H$ . Conversely, the duplicator wins if the spoiler is unable to win after any number of rounds.

With the above definition, we can now prove the equivalence between the outcome of a pebble game and the ability to distinguish non-isomorphic graphs using spectral invariant GNNs:

**Lemma 3.19. (Equivalence of pebble game and spectral invariant GNNs)** Given graphs  $G$  and  $H$  and the number of steps  $d \in \mathbb{N}$ , the spoiler cannot win the pebble game in  $d$  steps iff  $\chi_G^{\text{Spec},(d+1)}(G) = \chi_H^{\text{Spec},(d+1)}(H)$ .

We give a proof in Appendix B.4. Next, to identify counterexamples  $G$  and  $H$  for any  $F \notin \mathcal{F}^{\text{Spec},(d)}$  such that  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$  and  $\text{hom}(F, G) \neq \text{hom}(F, H)$ , we draw inspiration from a special class of graphs called Furer graphs (Furer, 2001), which is a principled approach to constructing pairs of non-isomorphic but structurally similar graphs. If graphs  $G$  and  $H$  are the Furer graph and twisted Furer graph constructed from the same base graph  $F$ , we show that the pebble game can be significantly simplified. Importantly, the simplified pebble game will be played on the base graph  $F$  instead of the complex Furer graphs, making the subsequent analysis much easier. Due to space constraints, a detailed description of the simplified pebble game is provided in Appendix B.5. We then establish the following lemma, which relates the simplified pebble game to spectral invariant GNNs:

**Lemma 3.20. (Equivalence of pebble game on Furer graphs and spectral invariant GNNs)** Given a base graph  $F$ , let  $G(F)$  and  $H(F)$  be the Furer graph and twisted Furer graph of  $F$ , respectively. Then, the spoiler cannot win the simplified pebble game on  $F$  in  $d$  steps iff  $\chi_G^{\text{Spec},(d+1)}(G(F)) = \chi_H^{\text{Spec},(d+1)}(H(F))$ .

Note that for any connected graph  $F$ ,  $\text{hom}(F, G(F)) \neq \text{hom}(F, H(F))$  (Roberson, 2022; Zhang et al., 2024a). Furthermore, we demonstrate that the spoiler has a winning strategy on  $F$  in  $d$  steps if and only if  $F$  is a parallel tree with parallel tree depth at most  $d + 1$  (see Appendix B.6). By combining these results with Lemma 3.20, we establish the following lemma:

**Lemma 3.21.** For any  $F \notin \mathcal{F}^{\text{Spec},(d)}$ , the spoiler cannot win the simplified pebble game on  $F$ . Consequently,  $\chi_G^{\text{Spec},(d)}(G(F)) = \chi_H^{\text{Spec},(d)}(H(F))$ .

This yields the second property in Theorem 3.3 and concludes the proof.

### 3.4 EXTENSIONS

So far, this paper mainly analyzes the standard spectral invariant GNNs, which refines *node features* based on projection information. In this subsection, we will show the flexibility of our proposed

432 homomorphism expressivity framework, which can also be used to analyze other spectral-based  
 433 GNN models such as higher-order spectral invariant GNNs.

### 435 3.4.1 HIGHER ORDER

436 Let us consider generalizing Section 2.1 to higher order spectral invariant GNNs. A natural update  
 437 rule of higher order spectral invariant GNN can be defined as follows:

438 **Definition 3.22 (Higher-Order Spectral Invariant GNN).** For any  $k \in \mathbb{N}_+$ , the  $k$ -order spectral  
 439 invariant GNN maintains a color  $\chi_G^{k\text{-Spec}}(\mathbf{u})$  for each vertex  $k$ -tuple  $\mathbf{u} = (u_1, \dots, u_k) \in V_G^k$ . Ini-  
 440 tially,  $\chi_G^{k\text{-Spec},(0)}(\mathbf{u}) = (\mathcal{P}(u_1, u_2), \dots, \mathcal{P}(u_1, u_k), \dots, \mathcal{P}(u_{k-1}, u_k))$ . In each iteration  $t + 1$ , the  
 441 color is updated as follows:

$$442 \chi_G^{k\text{-Spec},(t+1)}(\mathbf{u}) = \text{hash}(\chi_G^{k\text{-Spec},(t)}(\mathbf{u}), \{ \{ \chi_G^{k\text{-Spec},(t)}(v, u_2, \dots, u_k), \mathcal{P}(u_1, v) \} : v \in V_G \}, \dots, \\ 443 \{ \{ \chi_G^{k\text{-Spec},(t)}(u_1, u_2, \dots, u_{k-1}, v), \mathcal{P}(u_k, v) \} : v \in V_G \}).$$

444 Denote the stable color of vertex tuple  $\mathbf{u} \in V_G^k$  as  $\chi_G^{k\text{-Spec}}(\mathbf{u})$ . The graph representation is defined  
 445 as  $\chi_G^{k\text{-Spec}}(G) := \{ \{ \chi_G^{k\text{-Spec}}(\mathbf{u}) : \mathbf{u} \in V_G^k \}$ .

446 One can see that when  $k = 1$ , the above definition degenerates to the standard spectral invariant  
 447 GNN defined in Section 2.1. To illustrate the homomorphism expressivity of higher-order spectral  
 448 invariant GNNs, we extend the concept of strong nested ear decomposition (NED) introduced by  
 449 Zhang et al. (2024a) and define the parallel strong NED. Our main result is stated below:

450 **Theorem 3.23 (informal).** *A graph  $F$  is said to have a parallel  $k$ -order strong nested ear decompo-  
 451 sition (NED) if there exists a graph  $G$  such that  $G$  admits a strong NED and  $F$  can be obtained from  
 452  $G$  by replacing each edge  $\{u, v\} \in E_G$  with a parallel edge that has endpoints  $(u, v)$ . Then, the  
 453 homomorphism expressivity of  $k$ -order spectral invariant GNNs is the set of all graphs that admit a  
 454 parallel  $k$ -order strong NED.*

455 Due to space constraints, we leave the formal definition of  $k$ -order strong NED and the technical  
 456 proof of Theorem 3.23 to the Appendix.

### 462 3.4.2 SYMMETRIC POWER

463 To generalize spectrum and projection to higher order, another classic approach in the literature is  
 464 to use the symmetric power of a graph (also called the *token graph*). Audenaert et al. (2005) first  
 465 introduced the graph symmetric power to generalize eigenvalues into higher-order graph invariants.  
 466 The formal definition of the symmetric  $k$ -th power is presented as follows:

467 **Definition 3.24 (Symmetric Power).** For any  $k \in \mathbb{N}_+$  and graph  $G$ , the symmetric  $k$ -th power of  
 468  $G$ , denoted by  $G^{\{k\}}$ , is a graph where its vertices are  $k$ -subsets of  $V_G$ , and two subsets are adjacent  
 469 if and only if their symmetric difference is an edge in  $G$ .

470 Our homomorphism expressivity framework can be used to study the ability of mainstream GNNs  
 471 to encode the symmetric power of graphs. Our main result is stated as follows:

472 **Theorem 3.25.** *The Local  $2k$ -GNN defined in Morris et al. (2020); Zhang et al. (2024a) can encode  
 473 the symmetric  $k$ -th power. Specifically, for given graphs  $G$  and  $H$ , if  $G$  and  $H$  have the same  
 474 representation under Local  $2k$ -GNN, then  $G^{\{k\}}$  and  $H^{\{k\}}$  have the same representation under the  
 475 spectral invariant GNN defined in Section 2.1.*

476 **Discussions with prior work.** Regarding the expressive power of symmetric power, Alzaga et al.  
 477 (2008); Barghi & Ponomarenko (2009) gave the first upper bound, showing that if  $2k$ -FWL fails  
 478 to distinguish between two non-isomorphic graphs, then their symmetric  $k$ -th powers are cospec-  
 479 tral. However, it remains unclear whether the conclusion extends to the more powerful projection  
 480 information (beyond eigenvalues), or if the stated upper bound is tight. These open questions are  
 481 further highlighted in Zhang et al. (2024b). Our result answers both questions by bounding the  
 482 stronger refinement-based spectral invariant for the  $k$ -th symmetric power graphs to Local  $2k$ -GNN,  
 483 which is strictly weaker than 2-FWL (Zhang et al., 2024a). This offers a deeper understanding of  
 484 the capability of mainstream GNNs in encoding higher-order spectral information.

Table 1: Experimental results on homomorphism counting, real-world tasks and substructure count.

Model	Task	Homomorphism Count					ZINC		Substructure Count					
							Subset	Full

## 4 EXPERIMENT

In this section, we validate our theoretical findings through empirical experiments. We evaluate the performance of GNN models on both synthetic and real-world tasks. For the synthetic tasks, we assess the homomorphic counting power and subgraph counting power of the GNN models. These experiments serve to confirm our theoretical results, including Theorem 3.3 and Corollary 3.14. In addition, for the real-world task, we focus on molecular reaction prediction, specifically evaluating GNN performance on the ZINC dataset (Dwivedi et al., 2020). Our primary objective is not to achieve SOTA results but to validate our theoretical findings. We compare the performance of spectral invariant GNNs to both MPNNs and subgraph GNNs on the ZINC dataset. Details about model architectures are in Appendix D.

**Homomorphism Count** We use the benchmark dataset from Zhao et al. (2022) to evaluate the homomorphism expressivity of four mainstream GNN models. The reported performance is measured by the normalized Mean Absolute Error (MAE) on the test set. The empirical results are presented in Table 1. We can see that concerning homomorphism: (i) MPNN is unable to encode any of the five substructures, and none of the five substructures is a tree; (ii) Spectral invariant GNN can only encode the 1st and 2nd substructures; (iii) Subgraph GNN can encode the 1st, 2nd, and 3rd substructures; and (iv) Local 2-GNN can encode the 1st, 2nd, 3rd, and 4th substructures. The empirical results basically align with our theoretical findings.

**Subgraph Count** Cycle counting is a fundamental problem in chemical and biological tasks. Following the settings in Frasca et al. (2022); Zhang et al. (2023a); Huang et al. (2023), we evaluate the cycle counting power of four GNNs. The empirical results in Table 1 demonstrate that the spectral invariant GNN can accurately count 3-, 4-, 5-, and 6-cycles, indicating its strong performance in cycle counting tasks. This empirical result is also consistent with our theoretical predictions. Furthermore, we believe that a potential enhancement to our experimental results would be to evaluate the GNN models on additional datasets, including EXP, CSL, BREC (Wang & Zhang, 2023).

**Real-World Task** We evaluate our GNN models on the ZINC-subset and ZINC-full dataset (Dwivedi et al., 2020). Following the standard configuration, all models are constrained to a 500K parameter budget. The results show that the spectral invariant GNN outperforms MPNN while demonstrating comparable performance to the subgraph GNN on the real-world task. These findings are consistent with our theoretical predictions.

## 5 CONCLUSION

In this work, we investigate the expressive power of spectral invariant graph neural networks (GNNs). By leveraging the framework of homomorphism expressivity, we give a precise characterization the homomorphism expressivity of these networks. We then establish a comprehensive hierarchy of spectral invariant GNNs relative to other mainstream GNNs based on their homomorphism expressivity. Additionally, we analyze the subgraph counting capabilities of spectral invariant GNNs, with a focus on their ability to count essential substructures. Our results are extended to higher-order contexts and address additional problems related to spectral structures using our homomorphism framework. We demonstrate the significance of our findings by showing how our results extend previous work and address open problems identified in the literature. Finally, we conduct experiments to validate our theoretical results.

## A ADDITIONAL RELATED WORK

**Spectral Based Graph Neural Network.** Spectral invariants refer to eigenvalues, projection matrices, and other generalized spectral information. In recent studies, spectral invariants have gained significant attention in the fields of graph learning and graph theory (Fürer, 2010; Van Dam & Haemers, 2003; Haemers & Spence, 2004). For instance, a well-known conjecture proposed by Van Dam & Haemers (2003); Haemers & Spence (2004) posits that almost all graphs can be uniquely determined by their spectra, up to isomorphism. Given the importance and widespread application of graph spectral information (Bonchev, 2018), the machine learning community has also focused on analyzing the ability of graph neural networks (GNNs) to encode spectral information and on designing GNN models that incorporate more spectral features. As a result, several recent works have concentrated on the spectral-based design of GNNs (Bruna et al., 2013; Defferrard et al., 2016; Lim et al., 2023; Huang et al., 2024; Feldman et al., 2023; Zhang et al., 2024b). Specifically, Dwivedi et al. (2023; 2021); Kreuzer et al. (2021); Rampásek et al. (2022) have designed spectral GNNs by encoding Laplacian eigenvectors as absolute positional encodings. A key drawback of using Laplacian eigenvectors is the ambiguity in choosing eigenvectors; thus, follow-up works have sought to design GNNs that are invariant to the choice of eigenvectors. Lim et al. (2023) introduced BasisNet, which achieves spectral invariance for the first time using projection matrices. Huang et al. (2024) further generalized BasisNet by proposing the Spectral Projection Encoding (SPE), which performs soft aggregation across different eigenspaces, as opposed to the hard separation implemented in BasisNet.

In addition to the design of spectral-based GNNs, several recent works have also focused on analyzing the expressive power of spectral GNNs and comparing them with other mainstream GNN models. Balcilar et al. (2021) investigate the relationship between ChebNet (Defferrard et al., 2016) and the 1-WL test, demonstrating that for graphs with similar maximum eigenvalues, ChebNet is as expressive as 1-WL. Geerts & Reutter (2022) revisit this analysis and prove that CaleyNet (Levie et al., 2018) is bounded by the 2-WL test.

Black et al. (2024) introduced several new WL algorithms based on absolute and relative positional encodings (PE). The authors further established a bunch of equivalence relationships among these algorithms. Notably, there exists a strong connection between the proposed "stack of power of matrices" PE and Spectral Invariant GNNs. We can prove that the proposed  $(I, L, \dots, L^{2n-1})$ -WL (see Theorem 4.6 in Black et al. (2024)) is as expressive as spectral invariant GNNs with matrix  $L$ , and similarly,  $(I, A, \dots, A^{2n-1})$ -WL is as expressive as spectral invariant GNNs with the ordinary adjacency matrix. Therefore, all results in our paper can be used to understand the power of these WL variants. Since Zhang et al. (2024b) has shown that the expressive power of RD-WL is bounded by Spectral Invariant GNNs, it follows that the proposed  $L^\dagger$ -WL (see Theorem 4.6 in Black et al. (2024)) is also bounded in expressive power by Spectral Invariant GNNs. This conclusion reproduces their key result (Theorem 4.4 in Black et al. (2024)).

**Homomorphism Count and Subgraph Count.** Subgraph counting is a fundamental problem in chemical and biological tasks, as the ability to count subgraphs is strongly correlated with the performance of GNN in molecular prediction tasks. Kanatsoulis & Ribeiro studies subgraph counting power for a novel GNN framework, where classic message-passing GNNs are enhanced with random node features, and the GNN output is computed by taking the expectation over the introduced randomness. The paper demonstrates that such GNNs can learn to count various substructures, including cycles and cliques. These findings share similarities with our work, as both studies characterize the cycle-counting power of certain GNN models. Notably, the GNN framework proposed in Kanatsoulis & Ribeiro can count more complex substructures, such as 4-cliques and 8-cycles, which exceed the expressive power of 2-FWL.

Moreover, based on the foundational theory of Lovász (2012); Curticapean et al. (2017), it follows that the subgraph counting power of a GNN can be inferred from its ability to count homomorphisms (Seppelt, 2023; Zhang et al., 2024a). Consequently, recent research has also focused on the homomorphism counting power of GNNs. Dell et al. (2018) demonstrates that two graphs have the same representation under the  $k$ -WL algorithm if and only if the number of homomorphisms to the two graphs from any substructure with bounded tree width  $k$  is equal. Additionally, Zhang et al. (2024a) introduce the concept of homomorphism expressivity as a quantitative framework for assessing the expressive power of GNNs. This paper specifically focuses on the subgraph counting

power of spectral invariant GNNs. Related works in this area include Cvetkovic et al. (1997), which shows that the graph angles (which can be determined through projection) are capable of counting all cycles of length up to 5, and Lim et al. (2023), which demonstrates that GNNs can count cycles with up to 5 vertices. A detailed comparison of our results with these previous studies is provided in the main text.

## B PROOF OF THEOREM 3.3

### B.1 PREPARATION: PARALLEL TREE AND UNFOLDING TREE

#### B.1.1 ADDITIONAL EXPLANATION FOR PARALLEL TREE

For the reader’s convenience, we begin by restating the definition of the parallel tree, as introduced in the main paper.

**Definition B.1 (Parallel Edge):** We denote a graph  $G$  as a *parallel edge* if there exist vertices  $u, v \in V_G$  such that the edge set  $E_G$  can be partitioned into a sequence of simple paths  $P_1, \dots, P_m$ , where each path has endpoints  $(u, v)$ . We refer to  $(u, v)$  as the endpoints of the parallel edge  $G$ .

**Definition B.2 (Parallel Tree):** We define a graph  $F$  as a *parallel tree* if there exists a tree  $T$  such that we can obtain a graph isomorphic to  $F$  by replacing each edge  $(u, v) \in E_T$  with a parallel edge having endpoints  $(u, v)$ . We refer to  $T$  as the *parallel tree skeleton* of the graph  $F$ . Additionally, we denote the minimum depth of any parallel tree skeleton of  $F$  as the *parallel tree depth* of  $F$ .

We further define parallel tree decomposition for any parallel tree as follows:

**Definition B.3 (Parallel tree decomposition).** For a parallel tree  $F = (V_F, E_F)$ , its parallel tree decomposition involves constructing a rooted tree  $T^r = (V_{T^r}, E_{T^r})$  along with mapping functions  $\beta_{T^r}$  and  $\gamma_{T^r}$  that satisfy the following conditions:

1. The label function for nodes,  $\beta_{T^r} : V_{T^r} \rightarrow V_F$ , maps each node in  $T^r$  to a unique vertex in  $F$ .
2. Let  $\mathcal{E}_F$  denote the union of all paths in the graph  $F$ . The edge label function,  $\gamma_{T^r} : E_{T^r} \rightarrow 2^{\mathcal{E}_F}$ , satisfies the condition that for all  $(t_1, t_2) \in E_{T^r}$ , each  $P \in \gamma_{T^r}(t_1, t_2)$  is a path connecting  $\beta_{T^r}(t_1)$  and  $\beta_{T^r}(t_2)$ . Moreover, for each edge  $e \in E_F$ , there exists a unique tuple  $(t_1, t_2, P)$ , where  $(t_1, t_2) \in V_{T^r} \times V_{T^r}$  and  $P \in \gamma_{T^r}(t_1, t_2)$ , such that  $e$  lies on the path  $P$ .

We denote  $T^r = (V_{T^r}, E_{T^r}, \beta_{T^r}, \gamma_{T^r})$  as the decomposition skeleton of graph  $F$ , and the ordered pair  $(F, T^r)$  as a parallel-tree decomposed graph.

Let  $\mathcal{S}^{pt}$  denote the set of all parallel trees, and we use  $\mathcal{S}_d^{pt}$  to denote the set of all parallel trees whose parallel tree skeleton has depth at most  $d$ .

#### B.1.2 UNFOLDING TREE OF SPECTRAL INVARIANT GNN

We now introduce a process of constructing a parallel tree from any vertex of a given graph.

**Definition B.4 (Constructing an unfolding tree of spectral invariant GNN).** Given a graph  $G$ , vertex  $u \in V(G)$  and a non-negative integer  $d$ , the depth- $d$  spectral GNN unfolding tree of graph  $G$  at vertex  $u$ , denoted as  $(F_G^{(d)}(u), T_G^{(d)}(u))$ , is a parallel-tree decomposed graph constructed as follows: At the beginning,  $F = \{u\}$ , and  $T$  only has a root node  $r$  with  $\beta_{T^r}(r) = \{u\}$ . We can define a mapping  $\pi : V_F \rightarrow V_G$  as  $\pi(u) = u$ .

For each leaf node  $t$  in  $T^r$ , do the following procedure: Let  $\beta_{T^r}(t) = x$ . For each  $w \in V_G$ , add a fresh node  $t_w$  to  $T^r$  and designate  $t$  as its parent. Then, consider the following case:

1. If  $w \neq \pi(x)$ , add  $x_w$  to  $F$  and extend  $\pi$  with  $\pi(x_w) = w$ . We define  $\beta_{T^r}(t_w) = x_w$ . For every walk  $w = v_1, v_2, \dots, v_n = \pi(x)$  with  $n \leq |V_G|$ , where  $v_1 = \pi(x), v_n = w$ , we introduce a path  $x_{v_1}, x_{v_2}, \dots, x_{v_n}$  linking  $x_w$  and  $x$  to graph  $F$ , where  $x_{v_1} = x, x_{v_n} = x_w$ . We can also extend mapping  $\pi$  with  $\pi(x_{v_1}) = v_1, \pi(x_{v_2}) = v_2, \dots, \pi(x_{v_n}) = v_n$ . We define  $\gamma_{T^r}(t, t_w)$  to be the set of all path  $x_{v_1}, x_{v_2}, \dots, x_{v_n}$  connecting  $x$  and  $x_w$  introduced in this step.
2. If  $w = \pi(x)$ , we define  $\beta_{T^r}(t_w) = x$ . Similarly, for every walk  $w = v_1, v_2, \dots, v_n = \pi(x)$  with  $n \leq |V_G|$ , we introduce a loop  $x_{v_1}, x_{v_2}, \dots, x_{v_n}$  to graph  $F$ , where  $x_{v_1} = x = x_{v_n}$ . We can also extend mapping  $\pi$  with  $\pi(x_{v_1}) = v_1, \pi(x_{v_2}) = v_2, \dots, \pi(x_{v_n}) = v_n$ . We define

918  $\gamma_{T^r}(t, t_w)$  to be the set of all path  $x_{v_1}, x_{v_2}, \dots, x_{v_n}$  connecting  $x$  and  $x_w$  introduced in this  
 919 step.  
 920

921 We terminate the process once  $T^r$  becomes a complete tree of depth  $d$ .

922 The following fact is straightforward from the construction of the unfolding tree:

923 **Fact B.5.** *For any graph  $G$ , any vertex  $u \in V_G$ , and any non-negative integer  $D$ , there is a homo-*  
 924 *morphism from  $F_G^{(D)}(u)$  to  $G$ .*  
 925

926 With additional Explanation for parallel tree and construction of unfolding tree, we are now ready  
 927 to prove Theorem 3.3 step by step.  
 928

## 929 B.2 STEP 1: EQUIVALENCE OF ENCODING WALK INFORMATION AND SPECTRAL 930 INFORMATION

931 In this section, we aim to prove Lemma 3.17. The key idea is to use the Cayley-Hamilton theorem  
 932 to demonstrate that the walk-encoding GNN, as defined in Lemma 3.17, is equivalent to the spectral  
 933 invariant GNN.  
 934

### 935 B.2.1 PROOF OF LEMMA 3.17

936 **Lemma B.6.** *Let  $G = (V_G, E_G)$  be a graph, with its adjacency matrix denoted by  $\mathbf{A}$ . For*  
 937 *vertices  $x, y \in V_G$ , define  $\omega_G^k(x, y) = \mathbf{A}_{x,y}^k$  for all  $k \in \{0, 1, 2, \dots, |V_G|\}$ , which rep-*  
 938 *resents the number of  $k$ -walks from vertex  $x$  to vertex  $y$ . Define the tuple  $\omega_G^*(x, y) =$   
 939  $(\omega_G^0(x, y), \omega_G^1(x, y), \dots, \omega_G^{n-1}(x, y))$ , where  $n = |V_G|$ . Define the walk-encoding GNN with the  
 940 following update rule:  
 941*

$$942 \chi_G^{\text{Walk},(d+1)}(x) = \text{hash}(\chi_G^{\text{Walk},(d)}(x), \{\{\omega_G^*(x, y), \chi_G^{\text{Walk},(d)}(y)\} \mid y \in V_G\}).$$

943 *The walk-encoding GNN outputs a graph invariant  $\chi_G^{\text{Walk},(d)}(G) = \{\{\chi_G^{\text{Walk},(d)}(u) \mid u \in V_G\}\}$ .*  
 944 *For any graphs  $G$  and  $H$ , we have  $\chi_G^{\text{Walk},(d)}(G) = \chi_H^{\text{Walk},(d)}(H)$  if and only if  $\chi_G^{\text{Spec},(d)}(G) =$   
 945  $\chi_H^{\text{Spec},(d)}(H)$ .  
 946  
 947*

948 *Proof.* We begin by proving the following statement: If the spectra of graph  $G$  and graph  $H$  are  
 949 identical (denoted as  $(\lambda_1, \lambda_2, \dots, \lambda_m)$ ), then for  $x, u \in V_G$  and  $y, v \in V_H$ ,  $\mathcal{P}(x, u) = \mathcal{P}(y, v)$  if  
 950 and only if  $\omega_G^*(x, u) = \omega_H^*(y, v)$ .  
 951

- 952 1. First, we prove that if  $\mathcal{P}(x, u) = \mathcal{P}(y, v)$ , then  $\omega_G^*(x, u) = \omega_H^*(y, v)$ .

953 By the properties of diagonalizable matrices, for any  $k \in \{1, 2, \dots, |V_G|\}$ , we have:

$$954 \omega_G^k(x, u) = \lambda_1^k \mathbf{P}_{\lambda_1}(x, u) + \lambda_2^k \mathbf{P}_{\lambda_2}(x, u) + \dots + \lambda_m^k \mathbf{P}_{\lambda_m}(x, u).$$

955 Therefore, if

$$956 \mathbf{P}_{\lambda_r}(x, u) = \mathbf{P}_{\lambda_r}(y, v), \quad \forall r \in [m],$$

957 it follows that:

$$958 \omega_G^k(x, u) = \sum_{r=1}^m \lambda_r^k \mathbf{P}_{\lambda_r}(x, u) = \sum_{r=1}^m \lambda_r^k \mathbf{P}_{\lambda_r}(y, v) = \omega_H^k(y, v).$$

959 Thus, we have proven the first direction of the statement.

- 960 2. Now, we prove that if  $\omega_G^*(x, u) = \omega_H^*(y, v)$ , then  $\mathcal{P}(x, u) = \mathcal{P}(y, v)$ .

961 Let  $\mathbf{A}_G$  and  $\mathbf{A}_H$  denote the adjacency matrices of graphs  $G$  and  $H$ , respectively. By the Cayley-  
 962 Hamilton theorem, the minimal annihilating polynomial of matrix  $\mathbf{A}_G$  is given by:

$$963 f(\lambda) = (\lambda - \lambda_1)(\lambda - \lambda_2) \cdots (\lambda - \lambda_m).$$

964 For each  $r \in \{1, 2, \dots, m\}$ , the eigenspace corresponding to eigenvalue  $\lambda_r$  is  $\mathbf{Ker}(\lambda_r I - \mathbf{A}_G)$ .  
 965 Since:

$$966 \mathbb{R}^n = \mathbf{Ker}(\lambda_1 I - \mathbf{A}_G) \oplus \mathbf{Ker}(\lambda_2 I - \mathbf{A}_G) \oplus \dots \oplus \mathbf{Ker}(\lambda_m I - \mathbf{A}_G),$$

1024  
1025

for each  $r \in \{1, 2, \dots, m\}$ , the projection matrix onto the kernel space  $\mathbf{Ker}(\lambda_r I - \mathbf{A}_G)$  is:

$$f_r(\mathbf{A}_G) = \prod_{j \neq r} (\lambda_j I - \mathbf{A}_G) = \mathbf{P}_{\lambda_r}.$$

Therefore, there exist coefficients  $c_0^r, \dots, c_{m-1}^r$  such that:

$$\begin{aligned} \mathbf{P}_{\lambda_r}(x, u) &= c_0^r \cdot \omega_G^0(x, u) + c_1^r \cdot \omega_G^1(x, u) + \dots + c_{m-1}^r \cdot \omega_G^{m-1}(x, u), \\ \mathbf{P}_{\lambda_r}(y, v) &= c_0^r \cdot \omega_H^0(y, v) + c_1^r \cdot \omega_H^1(y, v) + \dots + c_{m-1}^r \cdot \omega_H^{m-1}(y, v). \end{aligned}$$

Finally, we conclude that if  $\omega_G^*(x, u) = \omega_H^*(y, v)$ , then  $\mathcal{P}(x, u) = \mathcal{P}(y, v)$  for all  $x, u \in V_G$  and  $y, v \in V_H$ .

Armed with the statement proven above, we are now prepared to prove Lemma 3.17. We will prove the two directions of the lemma separately as follows:

1. First, we prove that if  $\chi_G^{\text{Spec}}(G) = \chi_H^{\text{Spec}}(H)$ , then  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$ . To do so, it suffices to show that for all  $t \in \mathbb{N}$ , if  $\chi_G^{\text{Spec},(t)}(u) = \chi_H^{\text{Spec},(t)}(v)$  for all  $(u, v) \in V_G \times V_H$ , then  $\chi_G^{\text{Walk},(t)}(u) = \chi_H^{\text{Walk},(t)}(v)$ .

We prove this by induction. Initially, the statement holds trivially for  $t = 0$ . We then assume the statement holds for  $t = d$  and aim to prove it for  $t = d + 1$ . If  $\chi_G^{\text{Spec},(d+1)}(u) = \chi_H^{\text{Spec},(d+1)}(v)$ , then the following conditions are satisfied:

$$\begin{aligned} \chi_G^{\text{Spec},(d)}(u) &= \chi_H^{\text{Spec},(d)}(v), \\ \{(\mathcal{P}(u, x), \chi_G^{\text{Spec},(d)}(x)) \mid x \in V_G\} &= \{(\mathcal{P}(v, y), \chi_H^{\text{Spec},(d)}(y)) \mid y \in V_H\}. \end{aligned} \quad (1)$$

For any  $x \in V_G$  and  $y \in V_H$ , if  $(\mathcal{P}(u, x), \chi_G^{\text{Spec},(d)}(x)) = (\mathcal{P}(v, y), \chi_H^{\text{Spec},(d)}(y))$ , then by our previous result and the induction hypothesis, we have:

$$(\omega_G^*(u, x), \chi_G^{\text{Walk},(d)}(x)) = (\omega_H^*(v, y), \chi_H^{\text{Walk},(d)}(y)). \quad (2)$$

By combining equation 1 and equation 2, we conclude:

$$\begin{aligned} \chi_G^{\text{Walk},(d)}(u) &= \chi_H^{\text{Walk},(d)}(v), \\ \{(\omega_G^*(u, x), \chi_G^{\text{Walk},(d)}(x)) \mid x \in V_G\} &= \{(\omega_H^*(v, y), \chi_H^{\text{Walk},(d)}(y)) \mid y \in V_H\}. \end{aligned}$$

Thus, we conclude that  $\chi_G^{\text{Walk},(d+1)}(u) = \chi_H^{\text{Walk},(d+1)}(v)$ . Therefore, we have proven that  $\chi_G^{\text{Spec}}(G) = \chi_H^{\text{Spec}}(H)$  implies  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$ .

2. Now, we prove the converse: if  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$ , then  $\chi_G^{\text{Spec}}(G) = \chi_H^{\text{Spec}}(H)$ . Initially,  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$  implies  $\{(\omega_G^*(u, u), \chi_G^{\text{Walk},(1)}(u)) \mid u \in V_G\} = \{(\omega_H^*(v, v), \chi_H^{\text{Walk},(1)}(v)) \mid v \in V_H\}$ . If  $\chi_G^{\text{Walk},(1)}(u) = \chi_H^{\text{Walk},(1)}(v)$ , then  $\omega_G^*(u, u) = \omega_H^*(v, v)$ . This leads to:

$$\{(\omega_G^*(u, u) \mid u \in V_G\} = \{(\omega_H^*(v, v) \mid v \in V_H\}.$$

Hence, we derive that for all  $k \in [n]$ :

$$\text{tr}(\mathbf{A}_G^k) = \sum_{u \in V_G} \mathbf{A}_G^k(u, u) = \sum_{u \in V_G} \omega_G^k(u, u) = \sum_{v \in V_H} \omega_H^k(v, v) = \sum_{v \in V_H} \mathbf{A}_H^k(v, v) = \text{tr}(\mathbf{A}_H^k).$$

By standard results from linear algebra, the spectra of graphs  $G$  and  $H$  must be identical.

Similar to the first direction, we now prove that for all  $t \in \mathbb{N}$ , if  $\chi_G^{\text{Walk},(t)}(u) = \chi_H^{\text{Walk},(t)}(v)$  for all  $(u, v) \in V_G \times V_H$ , then  $\chi_G^{\text{Spec},(t)}(u) = \chi_H^{\text{Spec},(t)}(v)$ .

We again proceed by induction. Initially, the statement holds trivially for  $t = 0$ . Assuming the statement holds for  $t = d$ , we aim to prove it for  $t = d + 1$ . If  $\chi_G^{\text{Walk},(d+1)}(u) = \chi_H^{\text{Walk},(d+1)}(v)$ , we have:

$$\begin{aligned} \chi_G^{\text{Walk},(d)}(u) &= \chi_H^{\text{Walk},(d)}(v), \\ \{(\omega_G^*(u, x), \chi_G^{\text{Walk},(d)}(x)) \mid x \in V_G\} &= \{(\omega_H^*(v, y), \chi_H^{\text{Walk},(d)}(y)) \mid y \in V_H\}. \end{aligned}$$

1026 According to the statement proven earlier, for any  $x \in V_G$  and  $y \in V_H$ ,  $\omega_G^*(u, x) = \omega_H^*(v, y)$   
 1027 implies that  $\mathcal{P}(u, x) = \mathcal{P}(v, y)$ . Thus, we obtain:

$$1028 \chi_G^{\text{Spec},(d)}(u) = \chi_H^{\text{Spec},(d)}(v),$$

$$1029 \{\{\mathcal{P}(u, x), \chi_G^{\text{Spec},(d)}(x)\} \mid x \in V_G\} = \{\{\mathcal{P}(v, y), \chi_H^{\text{Spec},(d)}(y)\} \mid y \in V_H\}.$$

1032 Therefore, we conclude that  $\chi_G^{\text{Spec},(d+1)}(u) = \chi_H^{\text{Spec},(d+1)}(v)$ . Finally, we have proven that  
 1033  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$  implies  $\chi_G^{\text{Spec}}(G) = \chi_H^{\text{Spec}}(H)$ .

1035 By combining both directions, we conclude that for any two graphs  $G$  and  $H$ ,  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$   
 1036 if and only if  $\chi_G^{\text{Spec}}(G) = \chi_H^{\text{Spec}}(H)$ . Hence, the walk-encoding GNN is as expressive as the spectral-  
 1037 invariant GNN.

□

### 1040 B.3 STEP 2: FINDING THE HOMOMORPHIC EXPRESSIVITY

1042 We first define the isomorphism between parallel-tree decomposed graphs.

1043 **Definition B.7.** Given two parallel-tree decomposed graphs  $(F, T^r)$  and  $(\tilde{F}, \tilde{T}^r)$ , a pair of mappings  
 1044  $(\rho, \tau)$  is called an isomorphism from  $(F, T^r)$  to  $(\tilde{F}, \tilde{T}^r)$ , denoted by  $(F, T^r) \cong (\tilde{F}, \tilde{T}^r)$ , if the  
 1045 following hold:

- 1047 1.  $\rho$  is an isomorphism from  $F$  to  $\tilde{F}$ , while  $\tau$  is an isomorphism from  $T^r$  to  $\tilde{T}^r$  (ignoring labels  $\beta$   
 1048 and  $\gamma$ ).
- 1049 2. For any  $t \in V_{T^r}$ ,  $\rho(\beta_{T^r}(t)) = \beta_{\tilde{T}^r}(\tau(t))$ . Moreover, for any  $(t_1, t_2) \in E_{T^r}$ ,  $\rho(\gamma_{T^r}(t_1, t_2)) =$   
 1050  $\gamma_{\tilde{T}^r}(\tau(t_1), \tau(t_2))$

1051 **Theorem B.8.** For any two graphs  $G, H$ , any vertices  $u \in V_G$ ,  $x \in V_H$ , and any non-negative integer  
 1052  $D$ ,  $\chi_G^{\text{Walk},(D)}(u) = \chi_H^{\text{Walk},(D)}(x)$  iff there exists an isomorphism  $(\rho, \tau)$  from  $(F_G^{(D)}(u), T_G^{(D)}(u))$   
 1053 to  $(F_H^{(D)}(x), T_H^{(D)}(x))$  such that  $\rho(u) = x$ .

1055 *Proof.* The proof proceeds by induction on  $D$ . The base case is straightforward: for  $D = 0$ , the  
 1056 theorem holds trivially. Now assume the theorem holds for all  $D \leq d$ , and we will prove it for  
 1057  $D = d + 1$ .

1058 We first prove that  $\chi_G^{\text{Walk},(d+1)}(u) = \chi_H^{\text{Walk},(d+1)}(x)$  implies the existence of an isomorphism  
 1059  $(\rho, \tau)$  from  $(F_G^{(d+1)}(u), T_G^{(d+1)}(u))$  to  $(F_H^{(d+1)}(x), T_H^{(d+1)}(x))$  such that  $\rho(u) = x$ . Given that  
 1060  $\chi_G^{\text{Walk},(d+1)}(u) = \chi_H^{\text{Walk},(d+1)}(x)$ , it follows that:

$$1062 \{\{\omega_G^*(u, v), \chi_G^{\text{Walk},(d)}(v)\}_{v \in V_G}\} = \{\{\omega_H^*(x, y), \chi_H^{\text{Walk},(d)}(y)\}_{y \in V_H}\}.$$

1064 Let  $n = |V_G| = |V_H|$ , and denote  $V_G = \{v_1, v_2, \dots, v_n\}$ ,  $V_H = \{y_1, y_2, \dots, y_n\}$  such that:

$$1065 \omega_G^*(u, v_i) = \omega_H^*(x, y_i), \quad \chi_G^{\text{Walk},(d)}(v_i) = \chi_H^{\text{Walk},(d)}(y_i) \quad \text{for all } i \in [n].$$

1067 By the definition of tree unfolding, we have:

$$1068 F_G^{(d+1)}(u) = \left( \bigcup_{v_i} F_G^{(d)}(v_i) \right) \cup F_G^{(1)}(u), \quad F_H^{(d+1)}(x) = \left( \bigcup_{y_i} F_H^{(d)}(y_i) \right) \cup F_H^{(1)}(x),$$

1071 where we use  $\cup$  to represent graph union. By the inductive hypothesis, there exists an isomor-  
 1072 phism  $(\rho_i, \tau_i)$  from  $(F_G^{(d)}(v_i), T_G^{(d)}(v_i))$  to  $(F_H^{(d)}(y_i), T_H^{(d)}(y_i))$  such that  $\rho_i(v_i) = y_i$ . Addition-  
 1073 ally, since  $\omega_G^*(u, v_i) = \omega_H^*(x, y_i)$ ,  $F_G^{(1)}(u)$  is isomorphic to  $F_H^{(1)}(x)$ . Therefore, by merging all  
 1074  $\rho_i$  and  $\tau_i$  into  $\tilde{\rho}$  and  $\tilde{\tau}$ , and constructing an approximate mapping between tree nodes at depth no  
 1075 more than 1 in  $T_G^{(d+1)}(u)$  and  $T_H^{(d+1)}(x)$ , it follows that  $(\tilde{\rho}, \tilde{\tau})$  is a well-defined isomorphism from  
 1076  $(F_G^{(d+1)}(u), T_G^{(d+1)}(u))$  to  $(F_H^{(d+1)}(x), T_H^{(d+1)}(x))$ , satisfying  $\tilde{\rho}(u) = x$ .

1078 Next, we prove that if there exists an isomorphism  $(\rho, \tau)$  between the parallel-tree decom-  
 1079 posed graphs  $(F_G^{(d+1)}(u), T_G^{(d+1)}(u))$  and  $(F_H^{(d+1)}(x), T_H^{(d+1)}(x))$  such that  $\rho(u) = x$ , then

1080  $\chi_G^{\text{Walk},(d+1)}(u) = \chi_H^{\text{Walk},(d+1)}(x)$ . Since  $\tau$  is an isomorphism from  $T_G^{(d+1)}(u)$  to  $T_H^{(d+1)}(x)$ , it maps  
 1081 all depth-1 nodes in  $T_G^{(d+1)}(u)$  to depth-1 nodes in  $T_H^{(d+1)}(x)$ . Let  $s_1, s_2, \dots, s_n$  be the depth-1  
 1082 nodes in  $T_G^{(d+1)}(u)$ , and  $t_1, t_2, \dots, t_n$  be the corresponding nodes in  $T_H^{(d+1)}(x)$ . For  $i \in [n]$ , we de-  
 1083 note the subtree induced by  $s_i$  and its descendants as  $T_{G,s_i}^{(d+1)}(u)$ , and similarly, the subtree induced  
 1084 by  $t_i$  and its descendants as  $T_{H,t_i}^{(d+1)}(x)$ . Additionally, we define the subgraph of  $F_G^{(d+1)}(u)$  induced  
 1085 by  $T_{G,s_i}^{(d+1)}(u)$  as  $F_{G,s_i}^{(d+1)}(u)$ . Likewise, we define the subgraph of  $F_H^{(d+1)}(x)$  induced by  $T_{H,t_i}^{(d+1)}(x)$   
 1086 as  $F_{H,t_i}^{(d+1)}(x)$ . Without loss of generality, we assume the following:

- 1087 •  $\tau$  is an isomorphism from the subtree  $T_{G,s_i}^{(d+1)}(u)$  to  $T_{H,t_i}^{(d+1)}(x)$ .
- 1088 • For all  $s \in V_{T_{G,s_i}^{(d+1)}(u)}$ ,  $\rho(\beta_{T_{G,s_i}^{(d+1)}(u)}(s)) = \beta_{T_{H,t_i}^{(d+1)}(x)}(\tau(s))$ .
- 1089 • For all  $e \in E_{T_{G,s_i}^{(d+1)}(u)}$ ,  $\rho(\gamma_{T_{G,s_i}^{(d+1)}(u)}(e)) = \gamma_{T_{H,t_i}^{(d+1)}(x)}(\tau(e))$ .
- 1090 •  $\rho$  is an isomorphism between the subgraphs  $F_{G,s_i}^{(d+1)}(u)$  and  $F_{H,t_i}^{(d+1)}(x)$ .

1091 According to our assumption,  $(F_{G,s_i}^{(d+1)}(u), T_{G,s_i}^{(d+1)}(u))$  is isomorphic to  $(F_{H,t_i}^{(d+1)}(x), T_{H,t_i}^{(d+1)}(x))$ . Addi-  
 1092 tionally, by the definition of the unfolding tree,  $(F_{G,s_i}^{(d+1)}(u), T_{G,s_i}^{(d+1)}(u))$  is isomorphic to the depth- $d$   
 1093 unfolding tree  $(F_G^{(d)}(v_i), T_G^{(d)}(v_i))$  for some  $v_i \in V_G$ . Similarly,  $(F_{H,t_i}^{(d+1)}(x), T_{H,t_i}^{(d+1)}(x))$  is iso-  
 1094 morphic to  $(F_H^{(d)}(y_i), T_H^{(d)}(y_i))$  for some  $y_i \in V_H$ . By induction, we know that  $\chi_G^{\text{Walk},(d)}(v_i) =$   
 1095  $\chi_H^{\text{Walk},(d)}(y_i)$  and  $\omega_G^*(u, v_i) = \omega_H^*(x, y_i)$ . Therefore, we conclude:

$$1100 \left( \omega_G^*(u, v_i), \chi_G^{\text{Walk},(d)}(v_i) \right) = \left( \omega_H^*(x, y_i), \chi_H^{\text{Walk},(d)}(y_i) \right)$$

1101 for all  $i \in [n]$ , implying that:

$$1102 \left\{ \left( \omega_G^*(u, v_i), \chi_G^{\text{Walk},(d)}(v_i) \right) \right\}_{v \in V_G} = \left\{ \left( \omega_H^*(x, y_i), \chi_H^{\text{Walk},(d)}(y_i) \right) \right\}_{y \in V_H}. \quad (3)$$

1103 It remains to prove that  $\chi_G^{\text{Walk},(d)}(u) = \chi_H^{\text{Walk},(d)}(x)$ . To prove this, note that equation 3 implies that

$$1104 \left\{ \left( \omega_G^*(u, v_i), \chi_G^{\text{Walk},(d')}(v_i) \right) \right\}_{v \in V_G} = \left\{ \left( \omega_H^*(x, y_i), \chi_H^{\text{Walk},(d')}(y_i) \right) \right\}_{y \in V_H}.$$

1105 holds for all  $0 \leq d' \leq d$ . Combined this with the fact that  $\chi_G^{\text{Walk},(0)}(u) = \chi_H^{\text{Walk},(0)}(x)$ , we can  
 1106 incrementally prove that  $\chi_G^{\text{Walk},(d')}(u) = \chi_H^{\text{Walk},(d')}(x)$  for all  $d' \leq d + 1$ . We have thus concluded  
 1107 the proof. Thus, the proof is complete.  $\square$

1108 **Definition B.9.** Given a graph  $G$  and a parallel-tree decomposed graph  $(F, T^r)$ , we define the  
 1109 function  $\text{treeCount}((F, T^r), G)$  as the number of ordered pairs  $(u, d) \in V_G \times \mathbb{N}$  such that the  
 1110 depth- $d$  unfolding tree  $(F_G^{(d)}(u), T_G^{(d)}(u))$  at vertex  $u$  is isomorphic to  $(F, T^r)$ .

1111 **Corollary B.10.** For any graph  $G, H$ ,  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$  iff  $\text{treeCount}((F, T^r), G) =$   
 1112  $\text{treeCount}((F, T^r), H)$  holds for all parallel-tree decomposed graph  $(F, T^r)$ .

1113 *Proof.* We first prove one direction of the corollary. We aim to prove that if  $\chi_G^{\text{Walk}}(G) =$   
 1114  $\chi_H^{\text{Walk}}(H)$ , then  $\text{treeCount}((F, T^r), G) = \text{treeCount}((F, T^r), H)$ . If  $\chi_G^{\text{Walk}}(G) = \chi_H^{\text{Walk}}(H)$ , then  
 1115  $\left\{ \left\{ \chi_G^{\text{Walk}}(u) : u \in V_G \right\} \right\} = \left\{ \left\{ \chi_H^{\text{Walk}}(x) : x \in V_H \right\} \right\}$ . For each color  $c$  in the above multiset, pick  
 1116  $u \in V_G$  with  $\chi_G^{\text{Walk}}(u) = c$ . It follows that if  $(F, T^r) \cong (F_G^{(D)}(u), T_G^{(D)}(u))$  for some  $D$ , then  
 1117  $\text{treeCount}((F, T^r), G) = |\{u \in V_G : \chi_G^{\text{Walk}}(u) = c\}| = |\{x \in V_H : \chi_H^{\text{Walk}}(x) = c\}| =$   
 1118  $\text{treeCount}((F, T^r), H)$  by Theorem B.8. On the other hand, if  $(F, T^r) \not\cong (F_G^{(D)}(u), T_G^{(D)}(u))$   
 1119 for all  $u \in V_G$  and all  $D$ , then clearly  $\text{treeCount}((F, T^r), G) = \text{treeCount}((F, T^r), H) = 0$ .

1120 We then aim to prove the second direction of the corollary. If  $\text{treeCount}((F, T^r), G) =$   
 1121  $\text{treeCount}((F, T^r), H)$  holds for all parallel-tree decomposed graph  $(F, T^r)$ , it clearly holds for  
 1122 all  $(F_G^{(D)}(u), T_G^{(D)}(u))$  with  $u \in V_G$  and a sufficiently large  $D$ . This guarantees that for all color  
 1123  $c$ ,  $|\{u \in V_G : \chi_G^{\text{Walk}}(u) = c\}| = |\{x \in V_H : \chi_H^{\text{Walk}}(x) = c\}|$  by Theorem B.8. Therefore,  
 1124  $\left\{ \left\{ \chi_G^{\text{Walk}}(u) : u \in V_G \right\} \right\} = \left\{ \left\{ \chi_H^{\text{Walk}}(x) : x \in V_H \right\} \right\}$ , concluding the proof.  $\square$

**Definition B.11.** For parallel-tree decomposed graph  $(F, T^r)$ , we use  $\text{Dep}(T^r)$  to denote the depth of tree  $T$ . For any tree note  $t \in V_T$ , we use  $\text{dep}_T(t)$  to denote the depth of node  $t$  in  $T^r$ .

Using techniques similar to those in Corollary B.10, we can derive a finite-iteration version of Corollary B.10 as follows:

**Corollary B.12.** For any graphs  $G$  and  $H$ ,  $\chi_G^{\text{Walk},(d)}(G) = \chi_H^{\text{Walk},(d)}(H)$  if and only if  $\text{treeCount}((F, T^r), G) = \text{treeCount}((F, T^r), H)$  holds for all parallel-tree decomposed graphs  $(F, T^r)$  with  $\text{Dep}(T^r) \leq d$ .

In the following theorem, we will bridge homomorphic count with unfolding tree count. Before presenting the result, we first introduce some notations used to present the theorem.

**Definition B.13.** Given two parallel-tree decomposed graphs  $(F, T^r)$  and  $(\tilde{F}, \tilde{T}^r)$ , a pair of mappings  $(\rho, \tau)$  is called a *strong homomorphism* from  $(F, T^r)$  to  $(\tilde{F}, \tilde{T}^r)$  if it satisfies the following conditions: First,  $\tau$  is a homomorphism from  $T$  to  $\tilde{T}$ , ignoring the labels  $\beta$  and  $\gamma$ , and is depth-preserving, i.e.,  $\text{dep}_{T^r}(t) = \text{dep}_{\tilde{T}^r}(\tau(t))$  for all  $t \in V_T$ . Additionally,  $\rho$  is a homomorphism from  $F[\gamma_T(t_1, t_2)]$  to  $\tilde{F}[\gamma_{\tilde{T}}(\tau(t_1), \tau(t_2))]$ . Finally, the depth of  $T^r$  is equal to the depth of  $\tilde{T}^r$ .

We use  $\text{strHom}((F, T^r), (\tilde{F}, \tilde{T}^r))$  to denote the set of all strong homomorphism from  $(F, T^r)$  to  $(\tilde{F}, \tilde{T}^r)$ , and let  $\text{strhom}((F, T^r), (\tilde{F}, \tilde{T}^r)) = |\text{strHom}((F, T^r), (\tilde{F}, \tilde{T}^r))|$ .

**Theorem B.14.** Let  $(F, T^r)$  be parallel-tree decomposed graph and let  $G$  be a graph. We have

$$\text{hom}(F, G) = \sum_{(\tilde{F}, \tilde{T}^r) \in S^{pt}} \text{strhom}((F, T^r), (\tilde{F}, \tilde{T}^r)) \cdot \text{treeCount}((\tilde{F}, \tilde{T}^r), G)$$

*Proof.* We assume that  $\beta_{T^r}(r) = u$  for  $(F, T^r)$ , and the depth of  $(F, T^r)$  is  $d$ . Let  $x \in V_G$  be any vertex in  $G$ , and denote  $(F_G^{(d)}(x), T_G^{(d)}(x))$  as the depth- $d$  unfolding tree at  $x$ . We define  $S_1(x)$  as the set of all homomorphisms from  $F$  to  $G$  that map the vertex  $u \in V_F$  to  $x \in V_G$ . Furthermore, we define  $S_2(x)$  as the set of strong homomorphisms  $(\rho, \tau)$  from  $(F, T^r)$  to  $(F_G^{(d)}(x), T_G^{(d)}(x))$ , such that  $\rho(u) = x$ . Then Theorem B.14 is equivalent to the following equation:  $\sum_{x \in V_G} |S_1(x)| = \sum_{x \in V_G} |S_2(x)|$ . We will prove that  $|S_1(x)| = |S_2(x)|$  for all  $x \in V_G$ . Given  $x \in V_G$ , according to Fact B.5, there exists a homomorphism  $\pi$  from  $F_G^{(d)}(x)$  to graph  $G$ . Define a mapping  $\sigma$  such that  $\sigma(\rho, \tau) = \pi \circ \rho$  for all  $(\rho, \tau) \in S_2(x)$ . It suffices to prove that  $\sigma$  is a bijection from  $S_2(x)$  to  $S_1(x)$ .

We first prove that  $\sigma$  is a mapping from  $S_2(x)$  to  $S_1(x)$ . Since  $\rho$  is a homomorphism from  $F$  to  $F_G^{(d)}(x)$ , and  $\pi$  is a homomorphism from  $F_G^{(d)}(x)$  to  $G$ . The composition of homomorphism is still a homomorphism. Therefore,  $\pi \circ \rho$  is a homomorphism from  $F$  to graph  $G$ .

We then prove that  $\sigma$  is a surjection. For all  $g \in S_1(x)$ , we define a mapping  $(\rho, \tau)$  from  $(F, T^r)$  to  $(F_G^{(d)}(x), T_G^{(d)}(x))$  as follows. First define  $\rho(u) = x$  and set  $\tau(r)$  to be the root of  $(F_G^{(d)}(x), T_G^{(d)}(x))$ . Let  $v_1, v_2, \dots, v_m \in V_{T^r}$  be the tree nodes of depth 1. Similarly, by definition of the unfolding tree, let  $y_1, y_2, \dots, y_n \in V_{F_G^{(d)}(x)}$  be tree nodes of depth 1. For all  $i \in [m]$ , we denote  $\{P_{i1}, P_{i2}, \dots, P_{ia_i}\} = \gamma_{T^r}(u, v_i)$ , to be the paths associated with edge  $(u, v_i) \in E_{T^r}$ . Similarly, for  $i \in [n]$  we denote  $\{\tilde{P}_{i1}, \tilde{P}_{i2}, \dots, \tilde{P}_{ib_i}\} = \gamma_{T^r}(x, y_i)$  to be the paths associated with edge  $(x, y_i) \in E_{T_G^{(d)}(x)}$ . Since  $g$  and  $\pi$  are both homomorphism, we have:

- For every  $v_i (i \in [m])$ , there exists  $x_j (j \in [n])$ , such that  $g(\beta_{T^r}(v_i)) = \pi(\beta_{T_G^{(d)}(x)}(y_j)) = \tilde{z}_j$  for some  $\tilde{z}_j \in V_G$ .
- For every path  $P_{ik} \in \gamma_{T^r}(u, v_i) (k \in [a_i])$  linking  $u$  and  $\beta_{T^r}(v_i)$ , there exists  $\tilde{P}_{jl} (l \in [b_j])$  linking  $x$  and  $\beta_{T_G^{(d)}(x)}(y_j)$  such that  $g(P_{ik}) = \pi(\tilde{P}_{jl})$ .

We then define  $\rho(\beta_{T^r}(v_i)) = \beta_{T_G^{(d)}(x)}(y_j)$  and  $\rho(P_{ik}) = \tilde{P}_{jl}$  for each  $i \in [m]$  and  $k \in [a_i]$ . Based on the above two items, one can easily define  $\tau$  such that each node  $s$  in  $T^r$  of depth 1

is mapped by  $\tau$  to a node  $t$  in  $T_G^{(d)}(x)$  of the same depth, such that  $\rho(\beta_{T^r}(s)) = \beta_{T_G^{(d)}(x)}(t)$  and  $\rho(\gamma_{T^r}(r, s)) = \gamma_{T_G^{(d)}(x)}(x, t)$ . Continuing, we denote the subtree of  $T^r$  induced by  $s$  and all its descendants as  $T_s^r$ , and the subgraph of  $F$  induced by  $T_s^r$  as  $F_s$ . Similarly, we denote the subtree of  $T_G^{(d)}(x)$  induced by  $\tau(s)$  and its descendants as  $T_{G, \tau(s)}^{(d)}(x)$ , and the subgraph of  $F_G^{(d)}(x)$  induced by  $T_{G, \tau(s)}^{(d)}(x)$  as  $F_{G, \tau(s)}^{(d)}(x)$ . We can recursively define the image of  $\rho$  on  $F_s$  for each tree node of depth 1, following the same construction described above. This recursive definition holds because  $g$  remains a homomorphism from  $(F_s, T_s^r)$  to  $G$ , and  $\pi$  remains a homomorphism from  $(F_{G, \tau(s)}^{(d)}(x), T_{G, \tau(s)}^{(d)}(x))$  to  $G$ , with  $g(\beta_{T^r}(s)) = \pi(\beta_{T_G^{(d)}(x)}(\tau(s)))$ . By recursively applying this procedure, we can construct  $(\rho, \tau)$  such that it becomes a strong homomorphism (denoted  $\text{strHom}$ ) from  $(F, T^r)$  to  $(F_G^{(d)}(x), T_G^{(d)}(x))$ . Therefore, we have shown that for any  $g \in S_1(x)$ , there exists a preimage  $(\rho, \tau) \in S_2(x)$  such that  $\sigma(\rho, \tau) = g$ .

Finally, we prove that  $\sigma$  is an injection.

Let  $(\rho_1, \tau_1), (\rho_2, \tau_2) \in S_2(x)$  such that  $\pi \circ \rho_1 = \pi \circ \rho_2$ . Similar to previous item, we define  $v_1, v_2, \dots, v_m \in V_{T^r}$  to be the tree nodes of depth 1. Similarly, by definition of the unfolding tree, let  $y_1, y_2, \dots, y_n \in V_{T_G^{(d)}(x)}$  be tree nodes of depth 1.

- For all  $i \in [m]$ , we denote  $\{P_{i1}, P_{i2}, \dots, P_{ia_i}\} = \gamma_{T^r}(u, v_i)$ , to be the paths associated with edge  $(u, v_i) \in E_{T^r}$ . Similarly, for  $i \in [n]$  we denote  $\{\tilde{P}_{i1}, \tilde{P}_{i2}, \dots, \tilde{P}_{ib_i}\} = \gamma_{T^r}(x, y_i)$  to be the paths associated with edge  $(x, y_i) \in E_{T_G^{(d)}(x)}$ . For each  $i \in [m]$ , let  $j_1(i)$  and  $j_2(i)$  be indices satisfying  $\rho_1(w_i) = x_{j_1(i)}$  and  $\rho_2(w_i) = x_{j_2(i)}$ . It follows that  $\pi(x_{j_1(i)}) = \pi(x_{j_2(i)})$ . By the definition of unfolding tree, we must have  $x_{j_1(i)} = x_{j_2(i)}$ , and thus  $\rho_1(w_i) = \rho_2(w_i)$ .
- For each  $k \in [a_i]$ ,  $P_{ik} \in \gamma_{T^r}(u, v_i)$ , let  $l_1(k)$  and  $l_2(k)$  be indices satisfying  $\rho_1(P_{ik}) = \tilde{P}_{j_1 l_1(j)}$  and  $\rho_2(P_{ik}) = \tilde{P}_{j_2 l_2(j)}$ , where we use  $j$  to denote  $j = j_1(i) = j_2(i)$ . With similar analysis as the previous item, we have  $\pi(\tilde{P}_{j_1 l_1(j)}) = \pi(\tilde{P}_{j_2 l_2(j)})$ . By the definition of the unfolding tree, we must have  $\tilde{P}_{j_1 l_1(j)} = \tilde{P}_{j_2 l_2(j)}$ , and thus  $\rho_1(P_{ik}) = \rho_2(P_{ik})$ .

Next, we recursively apply the previously described procedure to the subtree induced by the tree node  $s$  at depth 1 and its descendants, following the same steps outlined earlier. Through this process, we can ultimately demonstrate that  $\rho_1 = \rho_2$ . Consequently,  $\sigma$  is injective.

Combining the above three parts completes the proof.  $\square$

**Theorem B.15.** Let  $(F, T^r)$  be parallel-tree decomposed graph with  $\text{Dep}(T^r) \leq d$  and let  $G$  be a graph. We have

$$\text{hom}(F, G) = \sum_{(\tilde{F}, \tilde{T}^r) \in \mathcal{S}_d^{pt}} \text{strhom}\left((F, T^r), (\tilde{F}, \tilde{T}^r)\right) \cdot \text{treeCount}\left((\tilde{F}, \tilde{T}^r), G\right)$$

*Proof.* According to the third condition in Definition B.13, for  $(F, T^r) \in \mathcal{S}_d^{pt}$  and  $(\tilde{F}, \tilde{T}^r) \in \mathcal{S}_d^{pt}$ , if  $\text{strhom}((F, T^r), (\tilde{F}, \tilde{T}^r)) \neq 0$ , then  $\text{Dep}(T^r) = \text{Dep}(\tilde{T}^r)$ . Therefore, we have  $(\tilde{F}, \tilde{T}^r) \in \mathcal{S}_d^{pt}$ . Thus, the conclusion of the lemma follows.  $\square$

**Definition B.16.** Given two parallel-tree decomposed graphs  $(F, T^r)$  and  $(\tilde{F}, \tilde{T}^r)$ , along with a strong homomorphism  $(\rho, \tau)$ , we define  $(\rho, \tau)$  as a *surjective strong homomorphism* if both  $\rho$  and  $\tau$  are surjective mappings, and as an *injective strong homomorphism* if both  $\rho$  and  $\tau$  are injective mappings. We denote the set of all surjective strong homomorphisms from  $(F, T^r)$  to  $(\tilde{F}, \tilde{T}^r)$  by  $\text{strSurj}((F, T^r), (\tilde{F}, \tilde{T}^r))$ , and further define  $\text{strsurj}((F, T^r), (\tilde{F}, \tilde{T}^r)) = |\text{strSurj}((F, T^r), (\tilde{F}, \tilde{T}^r))|$ . Similarly, we denote the set of all injective strong homomorphisms from  $(F, T^r)$  to  $(\tilde{F}, \tilde{T}^r)$  by  $\text{strInj}((F, T^r), (\tilde{F}, \tilde{T}^r))$ , and further define  $\text{strinj}((F, T^r), (\tilde{F}, \tilde{T}^r)) = |\text{strInj}((F, T^r), (\tilde{F}, \tilde{T}^r))|$ .

We now present the following lemma regarding the relationships between strong homomorphisms, surjective strong homomorphisms, and injective strong homomorphisms.

**Lemma B.17.** For any parallel-tree decomposed graph  $(F, T^r)$  and  $(\tilde{F}, \tilde{T}^s)$ , we have

$$\text{strhom} \left( (F, T^r), (\tilde{F}, \tilde{T}^s) \right) = \sum_{(\hat{F}, \hat{T}^t) \in \mathcal{S}^{\text{pt}}} \text{strsurj} \left( (F, T^r), (\hat{F}, \hat{T}^t) \right) \cdot \text{strinj} \left( (\hat{F}, \hat{T}^t), (\tilde{F}, \tilde{T}^s) \right) / \text{aut} \left( \hat{F}, \hat{T}^t \right),$$

where  $\text{aut}(\hat{F}, \hat{T}^t)$  denotes the number of automorphism of  $(\hat{F}, \hat{T}^t)$ . Here, the summation ranges over all non-isomorphic (parallel-tree decomposed) graphs in  $\mathcal{S}^{\text{pt}}$  and is well-defined as there are only a finite number of graphs making the value in the summation non-zero.

*Proof.* We initially define the set  $S$  as the set of triples  $((\hat{F}, \hat{T}^t), (\rho, \tau), (\phi, \psi))$  that satisfy  $(\hat{F}, \hat{T}^t) \in \mathcal{S}^{\text{pt}}$ ,  $(\rho, \tau) \in \text{strSurj}((F, T^r), (\hat{F}, \hat{T}^t))$ , and  $(\phi, \psi) \in \text{strInj}((\hat{F}, \hat{T}^t), (\tilde{F}, \tilde{T}^s))$ . We define a mapping  $\sigma$  such that  $\sigma((\hat{F}, \hat{T}^t), (\rho, \tau), (\phi, \psi)) = (\phi \circ \rho, \psi \circ \tau)$  for all  $((\hat{F}, \hat{T}^t), (\rho, \tau), (\phi, \psi)) \in S$ . Our goal is to prove that  $\sigma$  is a mapping from  $S$  to  $\text{strHom}((F, T^r), (\tilde{F}, \tilde{T}^s))$ . Moreover, we aim to show that  $\sigma((\hat{F}_1, \hat{T}_1^{t_1}), (\rho_1, \tau_1), (\phi_1, \psi_1)) = \sigma((\hat{F}_2, \hat{T}_2^{t_2}), (\rho_2, \tau_2), (\phi_2, \psi_2))$  if and only if there exists an isomorphism  $(\hat{\rho}, \hat{\tau})$  from  $(\hat{F}_1, \hat{T}_1^{t_1})$  to  $(\hat{F}_2, \hat{T}_2^{t_2})$  such that  $\hat{\rho} \circ \rho_1 = \rho_2$ ,  $\hat{\tau} \circ \tau_1 = \tau_2$ ,  $\phi_1 = \phi_2 \circ \hat{\rho}$ , and  $\psi_1 = \psi_2 \circ \hat{\tau}$ .

We will prove these statements one by one. We first prove that  $\sigma$  is a mapping from  $S$  to  $\text{strHom}((F, T^r), (\tilde{F}, \tilde{T}^s))$ . This simply follows from the fact that  $\text{strSurj}$  and  $\text{strInj}$  are both  $\text{strHom}$ , and the composition of two  $\text{strHoms}$  are still a  $\text{strHom}$ .

Next, we will prove that  $\sigma$  is surjective. Given  $(\tilde{\rho}, \tilde{\tau}) \in \text{strHom}((F, T^r), (\tilde{F}, \tilde{T}^s))$ , we define  $(\hat{F}, \hat{T}^t)$ ,  $(\rho, \tau)$ , and  $(\phi, \psi)$  as follows:

1. We define  $\hat{F}$  as the subgraph of  $\tilde{F}$  induced by  $\tilde{\rho}(V_F)$ , and we define  $\hat{T}^t$  as the subgraph of  $\tilde{T}^s$  induced by  $\tilde{\tau}^H(V_T)$ . We clearly have  $(\hat{F}, \hat{T}^t) \in \mathcal{S}^{\text{pt}}$ .
2. Let  $\rho = \tilde{\rho}$  and  $\tau = \tilde{\tau}$ . Obviously,  $(\rho, \tau)$  is a  $\text{strSurj}$  from  $(F, T^r)$  to  $(\hat{F}, \hat{T}^t)$ .
3. Define identity mappings  $\phi(u) = u$  for all  $u \in V_{\hat{F}}$  for  $\psi(t) = t$  for all  $t \in V_{\hat{T}^t}$ . Obviously,  $(\phi, \psi)$  is a  $\text{strInj}$  from  $(\hat{F}, \hat{T}^t)$  to  $(\tilde{F}, \tilde{T}^s)$ .

We clearly have  $\tilde{\rho} = \phi \circ \rho$  and  $\tilde{\tau} = \psi \circ \tau$ . Thus,  $\sigma$  is a surjection.

We will now prove that  $\sigma((\hat{F}_1, \hat{T}_1^{t_1}), (\rho_1, \tau_1), (\phi_1, \psi_1)) = \sigma((\hat{F}_2, \hat{T}_2^{t_2}), (\rho_2, \tau_2), (\phi_2, \psi_2))$  iff there exist an isomorphism  $(\hat{\rho}, \hat{\tau})$  from  $(\hat{F}_1, \hat{T}_1^{t_1})$  to  $(\hat{F}_2, \hat{T}_2^{t_2})$  such that  $\hat{\rho} \circ \rho_1 = \rho_2$ ,  $\hat{\tau} \circ \tau_1 = \tau_2$ ,  $\phi_1 = \phi_2 \circ \hat{\rho}$ ,  $\psi_1 = \psi_2 \circ \hat{\tau}$ . It suffices to prove only one direction, namely,  $\sigma((\hat{F}_1, \hat{T}_1^{t_1}), (\rho_1, \tau_1), (\phi_1, \psi_1)) = \sigma((\hat{F}_2, \hat{T}_2^{t_2}), (\rho_2, \tau_2), (\phi_2, \psi_2))$  implies that there exist an isomorphism  $(\hat{\rho}, \hat{\tau})$  from  $(\hat{F}_1, \hat{T}_1^{t_1})$  to  $(\hat{F}_2, \hat{T}_2^{t_2})$  such that  $\hat{\rho} \circ \rho_1 = \rho_2$ ,  $\hat{\tau} \circ \tau_1 = \tau_2$ ,  $\phi_1 = \phi_2 \circ \hat{\rho}$ ,  $\psi_1 = \psi_2 \circ \hat{\tau}$ .

1. We first prove that  $\hat{F}_1 \cong \hat{F}_2$  and  $\hat{T}_1^{t_1} \cong \hat{T}_2^{t_2}$ . For any  $u, v \in V_F$ , if  $\rho_1(u) \neq \rho_1(v)$ , then  $\phi_1 \circ \rho_1(u) \neq \phi_1 \circ \rho_1(v)$  since  $\phi$  is an injection. Therefore,  $\phi_2 \circ \rho_2(u) \neq \phi_2 \circ \rho_2(v)$ , and thus  $\rho_2(u) \neq \rho_2(v)$ . By symmetry, we also have that  $\rho_2(u) \neq \rho_2(v)$  implies  $\rho_1(u) \neq \rho_1(v)$ . This proves that  $\rho_1(u) = \rho_1(v)$  iff  $\rho_2(u) = \rho_2(v)$ . For any  $u, v \in V_F$ , if  $\{\rho_1(u), \rho_1(v)\} \in E_{\hat{F}_1}$ , then  $\{u, v\} \in E_F$  since  $\rho_1$  is a surjection. Therefore,  $\{\rho_2(u), \rho_2(v)\} \in E_{\hat{F}_2}$  since  $\rho_2$  is a homomorphism.
2. Consequently, there exist isomorphism  $\hat{\rho}$  and  $\hat{\tau}$  such that  $\hat{\rho} \circ \rho_1 = \rho_2$ ,  $\hat{\tau} \circ \tau_1 = \tau_2$ . For any node  $q \in V_T$ ,

$$\hat{\rho}(\beta_{\hat{T}_1}(\tau_1(q))) = \hat{\rho} \circ \rho_1(\beta_T(q)) = \rho_2(\beta_T(q)) = \beta_{\hat{T}_2}(\tau_2(q)) = \beta_{\hat{T}_2}(\hat{\tau} \circ \tau_1(q)).$$

Moreover, for any  $\{q_1, q_2\} \in E_T$ ,

$$\hat{\rho}(\gamma_{\hat{T}_1}(\tau_1(q_1, q_2))) = \hat{\rho} \circ \rho_1(\gamma_T(q_1, q_2)) = \rho_2(\gamma_T(q_1, q_2)) = \gamma_{\hat{T}_2}(\tau_2(q_1, q_2)) = \gamma_{\hat{T}_2}(\hat{\tau} \circ \tau_1(q_1, q_2)).$$

Since  $\tau_1$  is surjective,  $\tau_1(q)$  ranges over all nodes in  $\hat{T}_1^{t_1}$  when  $q$  ranges over  $V_T$ , and  $\tau_1(q_1, q_2)$  ranges over all edges in  $\hat{T}_1^{t_1}$  when  $(q_1, q_2)$  ranges over  $E_T$ . We thus conclude that  $(\rho, \tau)$  is an isomorphism from  $(\hat{F}_1, \hat{T}_1^{t_1})$  to  $(\hat{F}_2, \hat{T}_2^{t_2})$ .

- 1296 3. We finally prove that  $\phi_1 = \phi_2 \circ \hat{\rho}$  and  $\psi_1 = \psi_2 \circ \hat{\tau}$ . Pick any  $u \in V_F$ , we have  $\phi_2 \circ \hat{\rho}\rho_1(u) =$   
 1297  $\phi_2 \circ \rho_2(u) = \phi_1 \circ \rho_1(u)$ . Since  $\rho_1$  is surjective,  $\phi_1(u)$  ranges over all vertices in  $\hat{F}_1$  when  $u$   
 1298 ranges over  $V_F$ . This proves that  $\phi_1 = \phi_2 \circ \hat{\rho}$ . Following the same procedure, we can prove that  
 1299  $\psi_1 = \psi_2 \circ \hat{\tau}$ .

1300 Combining the above three items concludes the proof.  $\square$

1301  
 1302  
 1303 From Lemma B.17, we can also obtain the finite-iteration version of Lemma B.17 as follows:

1304 **Lemma B.18.** For any parallel-tree decomposed graph  $(F, T^r) \in \mathcal{S}_d^{pt}$  and  $(\tilde{F}, \tilde{T}^s) \in \mathcal{S}_d^{pt}$ , we  
 1305 have

$$1306 \text{strhom} \left( (F, T^r), (\tilde{F}, \tilde{T}^s) \right) = \sum_{(\hat{F}, \hat{T}^t) \in \mathcal{S}_d^{pt}} \text{strsurj} \left( (F, T^r), (\hat{F}, \hat{T}^t) \right) \cdot \text{strinj} \left( (\hat{F}, \hat{T}^t), (\tilde{F}, \tilde{T}^s) \right) / \text{aut} \left( \hat{F}, \hat{T}^t \right),$$

1307  
 1308  
 1309  
 1310  
 1311 *Proof.* According to the third condition in Definition B.13, for  $(\hat{F}, \hat{T}^r) \in \mathcal{S}_d^{pt}$ , if  
 1312  $\text{strsurj}((F, T^r), (\hat{F}, \hat{T}^t)) \cdot \text{strinj}((\hat{F}, \hat{T}^t), (\tilde{F}, \tilde{T}^s)) \neq 0$ , it follows that  $(\hat{F}, \hat{T}^r) \in \mathcal{S}_d^{pt}$ . Therefore,  
 1313 the conclusion of the lemma is immediate.  $\square$

1314  
 1315 **Definition B.19.** We can list all non-isomorphic parallel-tree decomposed graphs into an infinite  
 1316 sequence  $(F_1, T_1^{r1}), (F_2, T_2^{r2}), \dots$  with the following order.

- 1317 • The order requires  $|V_{T_i}| \leq |V_{T_j}|$  for any  $i < j$ .
- 1318 • If  $|V_{T_i}| = |V_{T_j}|$  for any  $i < j$ , then  $|F_{T_i}| \leq |F_{T_j}|$ .

1319 Then we define following function matrix and function vector based on the order defined above.

- 1320 1. Let  $f : \mathcal{S}_d^{pt} \times \mathcal{S}_d^{pt} \rightarrow \mathbb{N}$  be any mapping. Define the associated matrix  $M^f \in \mathbb{N}^{\mathbb{N}^+ \times \mathbb{N}^+}$ ,  
 1321 where  $A_{i,j}^f = f((F_i, T_i^{r_i}), (F_j, T_j^{r_j}))$ . Similarly, we consider the finite-iteration version. Let  
 1322  $f : \mathcal{S}_d^{pt} \times \mathcal{S}_d^{pt} \rightarrow \mathbb{N}$  be any mapping. Define the associated matrix  $M^f \in \mathbb{N}^{\mathbb{N}^+ \times \mathbb{N}^+}$ , where  
 1323  $M_{i,j}^{f,(d)} = f((F_i, T_i^{r_i}), (F_j, T_j^{r_j}))$ .
- 1324 2. Let  $g : \mathcal{S}_d^{pt} \times \mathcal{G} \rightarrow \mathbb{N}$  be any mapping. Given a graph  $G \in \mathcal{G}$ , define the (infinite) vector  
 1325  $l_G^g \in \mathbb{N}^{\mathbb{N}^+}$ , where  $l_{G,i}^g = g((F_i, T_i^{r_i}), G)$ . For the finite-iteration version, let  $g : \mathcal{S}_d^{pt} \times \mathcal{G} \rightarrow \mathbb{N}$   
 1326 be any mapping. Given a graph  $G \in \mathcal{G}$ , define the (infinite) vector  $l_G^{g,(d)} \in \mathbb{N}^{\mathbb{N}^+}$ , where  $l_{G,i}^{g,(d)} =$   
 1327  $g((F_i, T_i^{r_i}), G)$ .
- 1328 3. Let  $h : \mathcal{G} \times \mathcal{G} \rightarrow \mathbb{N}$  be any mapping. Given a graph  $G \in \mathcal{G}$ , define the (infinite) vector  $l_G^h \in \mathbb{N}^{\mathbb{N}^+}$ ,  
 1329 where  $l_{G,i}^h = h(F_i, G)$ . In the finite-iteration setting, let  $h : \mathcal{G} \times \mathcal{G} \rightarrow \mathbb{N}$  be any mapping. Given  
 1330 a graph  $G \in \mathcal{G}$ , define the (infinite) vector  $l_G^{h,(d)} \in \mathbb{N}^{\mathbb{N}^+}$ , where  $l_{G,i}^{h,(d)} = h(F_i, G)$ .

1331  
 1332 **Theorem B.20.** For any two graphs  $G$  and  $H$ , we have  $\text{hom}((F, T^r), G) = \text{hom}((F, T^r), H)$  for all  
 1333 parallel-tree decomposed graphs  $(F, T^r)$  iff  $\text{treeCount}((F, T^r), G) = \text{treeCount}((F, T^r), H)$  for  
 1334 all parallel-tree decomposed graphs. Similarly, in the finite-iteration setting,  $\text{hom}((F, T^r), G) =$   
 1335  $\text{hom}((F, T^r), H)$  holds for all  $(F, T^r) \in \mathcal{S}_d^{pt}$  iff  $\text{treeCount}((F, T^r), G) = \text{treeCount}((F, T^r), H)$   
 1336 for all  $(F, T^r) \in \mathcal{S}_d^{pt}$ .

1337  
 1338 *Proof.* We consider each direction separately.

- 1339 1. First, we prove that if  $\text{treeCount}((F, T^r), G) = \text{treeCount}((F, T^r), H)$  for all parallel-tree  
 1340 decomposed graphs, then  $\text{hom}((F, T^r), G) = \text{hom}((F, T^r), H)$  for all such graphs  $(F, T^r)$ .  
 1341 According to Theorem B.14, this result can be expressed in matrix form as  $l_G^{\text{hom}} = M^{\text{strhom}} \cdot$   
 1342  $l_G^{\text{treeCount}}$  and  $l_H^{\text{hom}} = M^{\text{strhom}} \cdot l_H^{\text{treeCount}}$  for all parallel trees  $F$ . This directly implies that  
 1343  $l_G^{\text{treeCount}} = l_H^{\text{treeCount}}$  leads to  $l_G^{\text{hom}} = l_H^{\text{hom}}$ . Similarly, in the finite-iteration setting, the result  
 1344 from Theorem B.15 can be rewritten in matrix form as  $l_G^{\text{hom},(d)} = M^{\text{strhom},(d)} \cdot l_G^{\text{treeCount},(d)}$ .  
 1345 Therefore, if  $l_G^{\text{treeCount},(d)} = l_H^{\text{treeCount},(d)}$ , it follows that  $l_G^{\text{hom},(d)} = l_H^{\text{hom},(d)}$ .

2. For the second direction of the lemma, it suffices to prove the finite-iteration setting, as the general case directly follows. According to Lemma B.18, we have the following equations:

$$\begin{aligned} \mathbf{l}_G^{\text{strhom},(d)} &= \mathbf{M}^{\text{strsurj},(d)} \cdot \mathbf{M}^{\text{strinj},(d)} \cdot (\mathbf{M}^{\text{aut},(d)})^{-1} \cdot \mathbf{l}_G^{\text{treeCount},(d)}, \\ \mathbf{l}_H^{\text{strhom},(d)} &= \mathbf{M}^{\text{strsurj},(d)} \cdot \mathbf{M}^{\text{strinj},(d)} \cdot (\mathbf{M}^{\text{aut},(d)})^{-1} \cdot \mathbf{l}_H^{\text{treeCount},(d)}. \end{aligned}$$

By simple observation,  $\mathbf{M}^{\text{aut}}$  is a diagonal matrix where all diagonal elements are positive integers. Moreover,  $\mathbf{M}^{\text{strinj}}$  is an upper triangular matrix with positive diagonal elements. This holds because  $\text{strinj}((F_i, T_i^{r_i}), (F_j, T_j^{r_j})) > 0$  only when  $|V_{T_i}| \leq |V_{T_j}|$ . Since  $\mathbf{M}^{\text{strsurj},(d)}$  is a lower triangular matrix with positive diagonal elements, it is invertible. Thus,

$$\mathbf{M}^{\text{strinj},(d)} \cdot \mathbf{l}_G^{\text{treeCount},(d)} = \mathbf{M}^{\text{strinj},(d)} \cdot \mathbf{l}_H^{\text{treeCount},(d)}.$$

Additionally, by the definition of an unfolding tree, there are only finitely many non-zero elements in both  $\mathbf{l}_G^{\text{treeCount},(d)}$  and  $\mathbf{l}_H^{\text{treeCount},(d)}$ , and the corresponding non-zero indices are restricted to a fixed (finite) set. In this case, the upper triangular matrix  $\mathbf{M}^{\text{strinj},(d)}$  reduces to a finite-dimensional matrix, so we conclude that  $\mathbf{l}_G^{\text{treeCount},(d)} = \mathbf{l}_H^{\text{treeCount},(d)}$ . By enumerating over all  $d \geq 0$ , we obtain that  $\mathbf{l}_G^{\text{treeCount}} = \mathbf{l}_H^{\text{treeCount}}$ .

Combining item 1 and item 2, we finish the proof of the lemma.  $\square$

## B.4 STEP 3: FINDING PEBBLE GAME FOR SPECTRAL INVARIANT GNN

In this section, we introduce the pebble game and demonstrate its equivalence to the expressive power of spectral invariant GNN.

### B.4.1 PEBBLE GAME

We first formally define the rules of pebble game.

**Definition B.21 (Pebble game for spectral invariant GNN).** The pebbling game is conducted on two graphs  $G = (V_G, E_G)$  and  $H = (V_H, E_H)$ . Initially, each graph is equipped with two distinct pebbles, denoted as  $u$  and  $v$ , which start off outside the graphs. The game involves two players: the *Spoiler* and the *duplicator*. We now describe the procedure of the game as follows:

- *Initialization:* The Spoiler first selects a non-empty subset  $V^S$  from either  $V_G$  or  $V_H$ , and the duplicator responds with a subset  $V^D$  from the other graph, ensuring that  $|V^D| = |V^S|$ . The duplicator loses the game if no feasible choice is available. The Spoiler places a pebble  $u$  on a vertex in  $V^D$ , and the duplicator places a corresponding pebble  $u$  in  $V^S$ . Similarly, the Spoiler and duplicator repeat the process to place two pebbles,  $v$ . Specifically, the Spoiler selects a non-empty subset  $V^S$  from either  $V_G$  or  $V_H$ , and the duplicator responds by selecting a subset  $V^D$  from the other graph, maintaining  $|V^S| = |V^D|$ . The Spoiler then places  $v$  on a vertex in  $V^D$ , while the duplicator places the corresponding  $v$  in  $V^S$ .
- *Main Process:* The game iteratively repeats the following steps, where, in each iteration, the Spoiler may choose freely between the following two actions:
  1. Action 1 (moving pebble  $v$ ): The Spoiler first selects a non-empty subset  $V^S$  from either  $V_G$  or  $V_H$ , and the duplicator responds with a subset  $V^D$  from the other graph, ensuring that  $|V^D| = |V^S|$ . The Spoiler then moves pebble  $v$  to a vertex in  $V^D$ , and the duplicator moves the corresponding pebble  $v$  to a vertex in  $V^S$ .
  2. Action 2 (moving pebble  $u$ ): The Spoiler first selects a non-empty subset  $V^S$  from either  $V_G$  or  $V_H$ , and the duplicator responds with a subset  $V^D$  from the other graph, ensuring that  $|V^D| = |V^S|$ . The Spoiler then moves pebble  $u$  to a vertex in  $V^D$ , and the duplicator moves the corresponding pebble  $u$  to a vertex in  $V^S$ .
- *Termination:* The Spoiler wins if, after a certain number of rounds,  $\omega_G^*(u, v)$  for graph  $G$  differs from  $\omega_H^*(u, v)$  for graph  $H$ . Conversely, the duplicator wins if the Spoiler is unable to achieve a win after any number of rounds.

## B.4.2 EQUIVALENCE BETWEEN SPECTRAL GNNs AND PEBBLING GAMES

**Lemma B.22.** *Let  $l \in \mathbb{N}$  be any integer. For any vertices  $u_G, v_G \in \mathcal{V}_G$  and  $u_H, v_H \in \mathcal{V}_H$ , if  $\chi_G^{\text{Walk},(l)}(u) \neq \chi_H^{\text{Walk},(l)}(v)$ , then the Spoiler can win the game in  $l - 1$  rounds when the two pebbles  $u$  are initially placed on vertices  $u_G \in V_G$  and  $u_H \in V_H$  in graphs  $G$  and  $H$ , respectively.*

*Proof.* The proof proceeds by induction on  $l$ . First, consider the base case where  $l = 0$ . In this case, the statement is trivially true.

Now, assume that the lemma holds for all  $l \leq L$ , and consider the case where  $l = L + 1$ . Suppose  $\chi_G^{\text{Walk},(L+1)}(u_G) \neq \chi_H^{\text{Walk},(L+1)}(u_H)$ . If  $\chi_G^{\text{Walk},(L)}(u_G) \neq \chi_H^{\text{Walk},(L)}(u_H)$ , then by the inductive hypothesis, Spoiler wins. Otherwise, we have

$$\{(\omega_G^*(u_G, v_G), \chi_G^{\text{Walk},(L)}(v_G)) : v_G \in \mathcal{V}_G\} \neq \{(\omega_H^*(u_H, v_H), \chi_H^{\text{Walk},(L)}(v_H)) : v_H \in \mathcal{V}_H\}.$$

Therefore, there exists a color  $c$  and  $x \in \mathbb{R}^{|V_G|}$  such that  $|\mathcal{C}_G(u_G, c, x)| \neq |\mathcal{C}_H(u_H, c, x)|$ , where

$$\mathcal{C}_G(u_G, c, x) = \left\{ v_G \in \mathcal{V}_G : \chi_G^{\text{Walk},(L)}(v_G) = c, \omega_G^*(u_G, v_G) = x \right\}.$$

If  $|\mathcal{C}_G(u_G, c, x)| > |\mathcal{C}_H(u_H, c, x)|$ , the Spoiler can select the vertex subset  $V^S = \mathcal{C}_G(u_G, c, x) \subset \mathcal{V}_G$ . Regardless of how the Duplicator responds with a subset  $V^D \subset \mathcal{V}_H$ , there exists a vertex  $v_H \in V^D$  such that  $(\omega_H^*(u_H, v_H), \chi_H^{\text{Walk},(L)}(v_H)) \neq (x, c)$ . The Spoiler then selects this vertex  $x^S = v_H$ , and no matter how the Duplicator responds with  $x^D = v_G \in V^S$ , we have either  $\omega_G^*(u_G, v_G) \neq \omega_H^*(u_H, v_H)$  or  $\chi_G^{\text{Walk},(L)}(v_G) \neq \chi_H^{\text{Walk},(L)}(v_H)$ . If  $\omega_G^*(u_G, v_G) \neq \omega_H^*(u_H, v_H)$ , the Spoiler wins the game immediately. If  $\chi_G^{\text{Walk},(L)}(v_G) \neq \chi_H^{\text{Walk},(L)}(v_H)$ , the remainder of the game is equivalent to one where the two pebbles  $u$  are initially placed on  $v_G \in V_G$  and  $v_H \in V_H$  in graphs  $G$  and  $H$  respectively. By the inductive hypothesis, the Spoiler wins the game.

If  $|\mathcal{C}_G(u_G, c, x)| < |\mathcal{C}_H(u_H, c, x)|$ , Spoiler can select the vertex subset  $V^S = \mathcal{C}_H(u_H, c, x) \subset \mathcal{V}_H$ , and the conclusion follows analogously.  $\square$

**Lemma B.23.** *For any vertices  $u_G \in \mathcal{V}_G$  and  $u_H \in \mathcal{V}_H$ , if  $\chi_G^{\text{Walk},(l+1)}(u_G) = \chi_H^{\text{Walk},(l+1)}(u_H)$ , then the Spoiler cannot win the game within  $l$  rounds when the two pebbles are initially placed on vertices  $u_G \in V_G$  and  $u_H \in V_H$  in graphs  $G$  and  $H$ , respectively.*

*Proof.* The proof proceeds by induction on  $l$ . The base case  $l = 0$  is trivially true. Now, assume the statement holds for  $l \leq L$ , and consider the case  $l = L + 1$ . Suppose  $\chi_G^{\text{Walk},(L+2)}(u_G) = \chi_H^{\text{Walk},(L+2)}(u_H)$ . Then,

$$\{(\omega_G^*(u_G, v_G), \chi_G^{\text{Walk},(L+1)}(v_G)) : v_G \in \mathcal{V}_G\} = \{(\omega_H^*(u_H, v_H), \chi_H^{\text{Walk},(L+1)}(v_H)) : v_H \in \mathcal{V}_H\}.$$

If Spoiler selects a subset  $V^S$ , and if  $V^S \subset \mathcal{V}_G$ , Duplicator can respond with a subset  $V^D \subset \mathcal{V}_H$  such that

$$\{(\omega_G^*(u_G, v_G), \chi_G^{\text{Walk},(L+1)}(v_G)) : v_G \in V^S\} = \{(\omega_H^*(u_H, v_H), \chi_H^{\text{Walk},(L+1)}(v_H)) : v_H \in V^D\}.$$

Similarly, if  $V^S \subset \mathcal{V}_H$ , Duplicator can respond with a subset  $V^D \subset \mathcal{V}_G$  such that

$$\{(\omega_G^*(u_G, v_G), \chi_G^{\text{Walk},(L+1)}(v_G)) : v_G \in V^D\} = \{(\omega_H^*(u_H, v_H), \chi_H^{\text{Walk},(L+1)}(v_H)) : v_H \in V^S\}.$$

In both cases, it is clear that  $|V^S| = |V^D|$ . Next, regardless of how Spoiler moves the pebble  $v$  to a vertex  $x^S \in V^D$ , Duplicator can always respond by moving the corresponding pebble  $v$  to a vertex  $x^D \in V^S$ , such that

$$\left( \omega_G^*(u_G, \tilde{v}_G), \chi_G^{\text{Walk},(L+1)}(\tilde{v}_G) \right) = \left( \omega_H^*(u_H, \tilde{v}_H), \chi_H^{\text{Walk},(L+1)}(\tilde{v}_H) \right),$$

where  $(\tilde{v}_G, \tilde{v}_H)$  represents the new positions of the pebbles. The remaining game is then equivalent to a game in which the two pebbles are initially placed on vertices  $\tilde{v}_G \in V_G$  and  $\tilde{v}_H \in V_H$  in graphs  $G$  and  $H$ , respectively.  $\square$

1458 Combining previous two lemmas, we have the following result:

1459 **Lemma B.24.** *Given graph  $G$  and  $H$ , Spoiler cannot win the pebble game in  $d$  steps iff*  
 1460  $\chi_G^{\text{Spec},(d)} = \chi_H^{\text{Spec},(d)}$ .  
 1461

1462 Therefore, we have proven Lemma 3.19 in the main paper.

## 1463 B.5 STEP 4: INTRODUCING FÜRER GRAPHS

1464 To continue, we draw introduce Fürer graphs, and we further prove that pebble games restricted on  
 1465 Fürer graphs can be greatly simplified.

### 1466 B.5.1 PROPERTIES OF FÜRER GRAPHS

1467 We first introduce the definition of Fürer graphs, introduced by Fürer (2001).

1471 **Definition B.25 (Fürer graphs).** Given any connected graph  $F = (V_F, E_F)$ , the Fürer graph  
 1472  $G(F) = (V_{G(F)}, E_{G(F)})$  is constructed as follows:  
 1473

$$1474 \quad V_{G(F)} = \{(x, X) : x \in V_F, X \subset N_F(x), |X| \bmod 2 = 0\},$$

$$1475 \quad E_{G(F)} = \{\{(x, X), (y, Y)\} \subset V_G : \{x, y\} \in E_F, (x \in Y \leftrightarrow y \in X)\}.$$

1476 Here,  $x \in Y \leftrightarrow y \in X$  holds when either  $(x \in Y \text{ and } y \in X)$  or  $(x \notin Y \text{ and } y \notin X)$  holds. For  
 1477 each  $x \in V_F$ , denote the set

$$1478 \quad \text{Meta}_F(x) := \{(x, X) : X \subset N_F(x), |X| \bmod 2 = 0\}, \quad (4)$$

1479 which is called the meta vertices of  $G(F)$  associated to  $x$ . Note that  $V_{G(F)} = \bigcup_{x \in V_F} \text{Meta}_F(x)$ .

1481 We next define an operation called “twist”:

1482 **Definition B.26 (Twist).** Let  $G(F) = (V_{G(F)}, E_{G(F)})$  be the Fürer graph of  $F = (V_F, E_F, \ell_F)$ , and  
 1483 let  $\{x, y\} \in E_F$  be an edge of  $F$ . The *twisted* Fürer graph of  $G(F)$  for edge  $\{x, y\}$ , is constructed  
 1484 as follows:  $\text{twist}(G(F), \{x, y\}) := (V_{G(F)}, E_{\text{twist}(G(F), \{x, y\})})$ , where  
 1485

$$1486 \quad E_{\text{twist}(G(F), \{x, y\})} := E_{G(F)} \Delta \{\{\xi, \eta\} : \xi \in \text{Meta}_F(x), \eta \in \text{Meta}_F(y)\},$$

1487 and  $\Delta$  is the symmetric difference operator, i.e.,  $A \Delta B = (A \setminus B) \cup (B \setminus A)$ . For an edge set  $S =$   
 1488  $\{e_1, \dots, e_k\} \subset E_F$ , we further define

$$1489 \quad \text{twist}(G(F), S) := \text{twist}(\dots \text{twist}(G(F), e_1) \dots, e_k). \quad (5)$$

1490 Note that Equation (5) is well-defined as the resulting graph does not depend on the order of edges  
 1491  $e_1, \dots, e_k$  for twisting.

1492 The following result is well-known (see e.g., Zhang et al., 2023a, Corollary I.5 and Lemma I.7):

1493 **Theorem B.27.** *For any connected graph  $F$  and any set  $S_1, S_2 \subset E_F$ ,  $\text{twist}(G(F), S_1) \simeq$   
 1494  $\text{twist}(G(F), S_2)$  iff  $|S_1| \bmod 2 = |S_2| \bmod 2$ .*

1495 We now present an essential property of Fürer graphs in terms of walk number:

1496 **Theorem B.28.** *Let  $G(F) = (V_G, E_G)$  be the Fürer graph of  $F = (V_F, E_F)$  and  
 1497  $\hat{G}(F) = \text{twist}(G(F), \mathcal{E})$  for some  $\mathcal{E} \subset E_F$ . For any  $(x, \mathcal{X}), (y, \mathcal{Y}) \in \mathcal{V}_G$ , and  $x =$   
 1498  $x_1, x_2, \dots, x_{n-1}, x_n = y \in V_F$ , the  $n$ -walk starting from  $(x, \mathcal{X})$ , ending at  $(y, \mathcal{Y})$  and passing  
 1499  $\text{Meta}_F(x_1), \text{Meta}_F(x_2), \dots, \text{Meta}_F(x_n)$  in sequence on  $G(F)$  is not equal to the one on  $\hat{G}(F)$ ,  
 1500 namely  $|S| \neq |\hat{S}|$  where*

$$1501 \quad S = \left\{ ((x_1, \mathcal{X}_1), (x_2, \mathcal{X}_2), \dots, (x_n, \mathcal{X}_n)) : \mathcal{X}_1 = \mathcal{X}, \mathcal{X}_n = \mathcal{Y} \right.$$

$$1502 \quad \left. , \{(x_i, \mathcal{X}_i), (x_{i+1}, \mathcal{X}_{i+1})\} \in E_{G(F)}, i = 1, 2, \dots, n-1 \right\}$$

$$1503 \quad \hat{S} = \left\{ ((x_1, \mathcal{X}_1), (x_2, \mathcal{X}_2), \dots, (x_n, \mathcal{X}_n)) : \mathcal{X}_1 = \mathcal{X}, \mathcal{X}_n = \mathcal{Y} \right.$$

$$1504 \quad \left. , \{(x_i, \mathcal{X}_i), (x_{i+1}, \mathcal{X}_{i+1})\} \in E_{\hat{G}(F)}, i = 1, 2, \dots, n-1 \right\}$$

1505 iff the degree of  $x_2, x_3, \dots, x_{n-1}$  all equals to 2 in base graph  $F$  and

$$1506 \quad |\{(x_i, x_{i+1})\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}| \equiv 1 \pmod{2}$$

1512 *Proof.* We separately prove the two direction of the theorem.  
1513

1514 1. We first prove one direction of the statement, namely if the degree of  $x_2, x_3, \dots, x_{n-1}$  all equals  
1515 to 2 in base graph  $F$  and  $|\{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}| \equiv 1 \pmod{2}$ , then  $|S| \neq |\hat{S}|$ .  
1516 If the degree of  $x_2, x_3, \dots, x_{n-1}$  all equals to 2 and  $|\{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}| \equiv$   
1517  $1 \pmod{2}$ , then  $|S| \neq |\hat{S}|$ , then we can obtain a precise description of  $S$  and  $\hat{S}$ , categorized  
1518 according to  $\mathcal{X}$  and  $\mathcal{Y}$ .

1519 (a) If  $x_2 \in \mathcal{X}$  and  $x_{n-1} \in \mathcal{Y}$ , then we have

$$1520 \quad S = \{((x, \mathcal{X}), (x_2, \{x, x_3\}), (x_3, \{x_2, x_4\}), \dots, (x_{n-1}, \{x_{n-2}, y\}), (y, \mathcal{Y}))\} \quad \hat{S} = \emptyset$$

1522 (b) If  $x_2 \notin \mathcal{X}$  and  $x_{n-1} \in \mathcal{Y}$ , we assume

$$1523 \quad \{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E} = \{\{x_{a_1}, x_{a_1+1}\}, \{x_{a_2}, x_{a_2+1}\}, \dots, \{x_{a_m}, x_{a_m+1}\}\},$$

1525 where  $m \equiv 1 \pmod{2}$ . Then we have

$$1527 \quad S = \emptyset \quad \hat{S} = \{((x, \mathcal{X}), (x_2, \emptyset) \dots, (x_{a_1}, \emptyset), (x_{a_1+1}, \{x_{a_1}, x_{a_1+2}\}), \dots,$$

$$1528 \quad (x_{a_2}, \{x_{a_2-1}, x_{a_2+1}\}), (x_{a_2+1}, \emptyset), \dots, (x_{n-1}, \{x_{n-2}, y\}), (y, \mathcal{Y}))\}$$

1530 (c) If  $x_2 \in \mathcal{X}$  and  $x_{n-1} \notin \mathcal{Y}$ , we still assume

$$1531 \quad \{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}$$

$$1532 \quad = \{\{x_{a_1}, x_{a_1+1}\}, \{x_{a_2}, x_{a_2+1}\}, \dots, \{x_{a_m}, x_{a_m+1}\}, a_1 < a_2, \dots, a_{m-1} < a_m\},$$

1534 where  $m \equiv 1 \pmod{2}$ . Then we have

$$1536 \quad S = \emptyset \quad \hat{S} = \{((x, \mathcal{X}), (x_2, \{x_1, x_3\}) \dots, (x_{a_1}, \{x_{a_1-1}, x_{a_1+1}\}), (x_{a_1+1}, \emptyset), \dots,$$

$$1537 \quad (x_{a_2}, \emptyset), (x_{a_2+1}, \{x_{a_2}, x_{a_2+2}\}), \dots, (x_{n-1}, \emptyset), (y, \mathcal{Y}))\}$$

1539 (d) If  $x_2 \notin \mathcal{X}$  and  $x_{n-1} \notin \mathcal{Y}$ , then we have

$$1540 \quad S = \{((x, \mathcal{X}), (x_2, \emptyset), (x_3, \emptyset), \dots, (x_{n-1}, \emptyset), (y, \mathcal{Y}))\} \quad \hat{S} = \emptyset$$

1542 We can see that for all cases  $|S| \neq |\hat{S}|$ . Therefore, we have proven that if the degree of  
1543  $x_2, x_3, \dots, x_{n-1}$  all equals to 2 in base graph  $F$  and  $|\{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}| \equiv$   
1544  $1 \pmod{2}$ , then  $|S| \neq |\hat{S}|$ .  
1545

1546 2. We now prove the other direction of the theorem. We prove that if the degree of  $x_2, x_3, \dots, x_{n-1}$   
1547 all equals to 2 and  $|\{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}| \equiv 0 \pmod{2}$ , then  $|S| = |\hat{S}|$ . Sim-  
1548 ilar to previous item, we separately consider the precise expression of  $S$  and  $\hat{S}$  categorized by  
1549  $\mathcal{X}$  and  $\mathcal{Y}$ . We first assume that

$$1550 \quad \{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}$$

$$1551 \quad = \{\{x_{a_1}, x_{a_1+1}\}, \{x_{a_2}, x_{a_2+1}\}, \dots, \{x_{a_m}, x_{a_m+1}\}, a_1 < a_2, \dots, a_{m-1} < a_m\},$$

1553 where  $m \equiv 0 \pmod{2}$ .

1555 (a) If  $x_2 \in \mathcal{X}$  and  $x_{n-1} \in \mathcal{Y}$ , then we have

$$1556 \quad S = \{((x, \mathcal{X}), (x_2, \{x, x_3\}), (x_3, \{x_2, x_4\}), \dots, (x_{n-1}, \{x_{n-2}, y\}), (y, \mathcal{Y}))\}$$

$$1557 \quad \hat{S} = \{((x, \mathcal{X}), (x_2, \{x_1, x_3\}) \dots, (x_{a_1}, \{x_{a_1-1}, x_{a_1+1}\}), (x_{a_1+1}, \emptyset), \dots,$$

$$1558 \quad (x_{a_2}, \emptyset), (x_{a_2+1}, \{x_{a_2}, x_{a_2+2}\}), \dots, (x_{n-1}, \{x_{n-2}, y\}), (y, \mathcal{Y}))\}.$$

1560 (b) If  $x_2 \notin \mathcal{X}$  and  $x_{n-1} \in \mathcal{Y}$ , then we obviously have

$$1562 \quad S = \emptyset \quad \hat{S} = \emptyset.$$

1564 (c) If  $x_2 \in \mathcal{X}$  and  $x_{n-1} \notin \mathcal{Y}$ , then we similarly have

$$1565 \quad S = \emptyset \quad \hat{S} = \emptyset.$$

- 1566 (d) If  $x_2 \notin \mathcal{X}$  and  $x_{n-1} \notin \mathcal{Y}$ ,  
 1567  $S = \{((x, \mathcal{X}), (x_2, \emptyset), (x_3, \emptyset), \dots, (x_{n-1}, \emptyset), (y, \mathcal{Y}))\}$   
 1568  $\hat{S} = \{((x, \mathcal{X}), (x_2, \emptyset), \dots, (x_{a_1}, \emptyset), (x_{a_1+1}, \{x_{a_1}, x_{a_1+2}\}), \dots, (x_{a_2}, \{x_{a_2-1}, x_{a_2+1}\}),$   
 1569  $(x_{a_2+1}, \emptyset), \dots, (x_{n-1}, \emptyset), (y, \mathcal{Y}))\}$ .  
 1570  
 1571

1572 We can see that for all cases  $|S| = |\hat{S}|$ . Therefore, we have proven that if the degrees of  
 1573  $x_2, x_3, \dots, x_{n-1}$  all equals to 2 and  $|\{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n-1\} \cap \mathcal{E}| \equiv 0 \pmod{2}$ ,  
 1574 then  $|S| = |\hat{S}|$ .

- 1575 3. We eventually prove that if the degrees of  $x_2, x_3, \dots, x_{n-1}$  do not all equals to 2, then  $|S| = |\hat{S}|$ .

1576 We use  $\omega_n^{\hat{G}(F)}((x, \mathcal{X}), \text{Meta}(x_2), \dots, \text{Meta}(x_{n-1}), (y, \mathcal{Y}))$  to denote the number of  $n$ -walk  
 1577 starting from  $(x, \mathcal{X})$ , ending at  $(y, \mathcal{Y})$  and passing  $\text{Meta}_F(x_1), \dots, \text{Meta}_F(x_n)$  sequentially in  
 1578 Fürer graph  $\hat{G}(F) = \text{twist}(G(F), \mathcal{E})$ . We use notation  $\deg_F(v)$  to denote the degree of  $v$  in  
 1579 graph  $F$ . We do induction on  $n$  to prove a stronger statement:

1580 If the degree of  $x_2, x_3, \dots, x_{n-1}$  do not all equals to 2, then there exists function  $f_n^F : V(F)^n \rightarrow$   
 1581  $\mathbb{N}$ , such that  $\omega_n^{\hat{G}(F)}((x, \mathcal{X}), \text{Meta}(x_2), \dots, \text{Meta}(x_{n-1}), (y, \mathcal{Y})) = f_n(x_1, x_2, \dots, x_n)$  for all  
 1582  $\mathcal{X} \in \mathcal{N}_F(x), \mathcal{Y} \in \mathcal{N}_F(y)$  and any  $\mathcal{E} \subset E_F$ .

1583 We first consider the case when  $n = 2$ . We can straightforwardly define function  $f_n^F$  as  
 1584  $f(x_1, x_2, x_3) = 2^{\deg(x_2)-3}$ .

1585 We now assume that the statement holds for  $n \leq N$ , we consider the case when  $n = N + 1$ .  
 1586 We separately consider two cases

- 1587 (a) Not all degrees of  $x_3, x_4, \dots, x_{n-1}$  equals to 2.  
 1588 The  $n$ -walk passing  $\text{Meta}_F(x_1), \dots, \text{Meta}_F(x_n)$  sequentially can be split into a 1-walk  
 1589 from  $(x, \mathcal{X})$  to  $\text{Meta}_F(x_2)$  and an  $n - 1$  walk passing  $\text{Meta}_F(x_2), \dots, \text{Meta}_F(x_n)$  se-  
 1590 quentially and ending at  $(y, \mathcal{Y})$ . According to the induction hypothesis, the number  
 1591 of  $n - 1$  walk passing  $\text{Meta}_F(x_2), \dots, \text{Meta}_F(x_n)$  sequentially and ending at  $(y, \mathcal{Y})$   
 1592 equals to  $f_{n-1}^F(x_2, x_3, \dots, x_n)$ . Since the number of 1-walk from  $(x, \mathcal{X})$  to  $\text{Meta}_F(x_2)$   
 1593 equals to  $2^{\deg_F(x_2)-2}$ , we can define function  $f_n^F$  as  $f_n^F(x_1, x_2, \dots, x_n) = 2^{\deg_F(x_2)-2} \cdot$   
 1594  $f_{n-1}^F(x_2, x_3, \dots, x_n)$ .  
 1595 (b) All degrees of  $x_3, x_4, \dots, x_{n-1}$  equals to 2. Then we have  $\deg_F(x_2) \geq 3$ . Then the number  
 1596 of  $n - 1$  walk passing  $\text{Meta}_F(x_2), \dots, \text{Meta}_F(x_n)$  sequentially and ending at  $(y, \mathcal{Y})$  equals  
 1597 to 1 or 0. Therefore, we can simply define function  $f_n^F$  as  $f_n^F = 2^{\deg_F(x_2)-3}$ .

1598 Combining the two items, we can conclude that if the degrees of  $x_2, x_3, \dots, x_{n-1}$   
 1599 do not all equals to 2, then there exists function  $f_n^F : V(F)^n \rightarrow \mathbb{N}$ , such that  
 1600  $\omega_n^{\hat{G}(F)}((x, \mathcal{X}), \text{Meta}(x_2), \dots, \text{Meta}(x_{n-1}), (y, \mathcal{Y})) = f_n(x_1, x_2, \dots, x_n)$  for all  $\mathcal{X} \in$   
 1601  $\mathcal{N}_F(x), \mathcal{Y} \in \mathcal{N}_F(y)$  and any  $\mathcal{E} \subset E_F$ .  
 1602

1603 Combining all previous analysis, we have proven the result of the theorem.  $\square$

## 1604 B.5.2 SIMPLIFIED PEBBLE GAME ON FÜRER GRAPHS

1605 **Definition B.29 (Connected components).** Let  $F = (V_F, E_F)$  be a connected graph, and  
 1606 let  $U \subset V_F$  be a set of vertices, referred to as separation vertices. We define two edges  
 1607  $\{u, v\}, \{x, y\} \in E_F$  as belonging to the same connected component if there exists a simple path  
 1608  $\{\{y_0, y_1\}, \{y_1, y_2\}, \dots, \{y_{k-1}, y_k\}\}$  such that  $\{y_0, y_1\} = \{u, v\}$ ,  $\{y_{k-1}, y_k\} = \{x, y\}$ , and  $y_i \notin U$   
 1609 for all  $i \in [1, k - 1]$ . It is straightforward to verify that this relation between edges induces an *equiv-*  
 1610 *alence relation*. Consequently, the edge set  $E_F$  can be partitioned into disjoint subsets, denoted by  
 1611  $\text{CC}_F(U) = \{P_i : i \in [m]\}$ , where each  $P_i \subset E_F$  represents a connected component for some  $m$ .

1612 **Definition B.30 (Simplified Pebble Game).** The simplified pebble game is defined as follows. Let  
 1613  $F = (V_F, E_F)$  represent the base graph of a proper Fürer graph. The game is played on  $F$  with  
 1614 two pebbles,  $u$  and  $v$ , each of a different type. Initially, both pebbles are placed outside the graph  
 1615  $F$ . The game begins with Spoiler placing pebble  $u$  on any vertex of  $F$ , while pebble  $v$  remains  
 1616 outside the graph. The game then proceeds in cycles, following these steps: Spoiler places pebble  $v$   
 1617 on any vertex of  $F$ , swaps the positions of  $u$  and  $v$ , and then places pebble  $v$  back outside the graph.  
 1618 Duplicator, on the other hand, maintains a subset  $Q$  of connected components, where  $Q \subset \text{CC}_S(F)$   
 1619 and  $S$  is the set of vertices in  $F$  where pebbles  $u$  and  $v$  are currently placed.

When Spoiler places a pebble on a vertex of  $F$ , one of two scenarios occurs. If  $CC_S(F)$  remains unchanged, Duplicator takes no action. However, if the new pebble placement causes a connected component to split into smaller regions, Duplicator updates  $\mathcal{Q}$  by replacing any original component  $\mathcal{P} \subset E_F$  that splits into  $\mathcal{P}_1, \dots, \mathcal{P}_k$  (where  $\bigcup_{i=1}^k \mathcal{P}_i = \mathcal{P}$ ) with a subset of the newly formed components. That is,  $\tilde{\mathcal{Q}} = (\mathcal{Q} \setminus \mathcal{P}) \cup \{\mathcal{P}_{j_1}, \dots, \mathcal{P}_{j_l}\}$  for some  $j_1, \dots, j_l \in [k]$ , ensuring that  $|\tilde{\mathcal{Q}}| \equiv 1 \pmod{2}$ . In other words, Duplicator removes the old component  $\mathcal{P}$  (if present) and adds some of the new components while preserving the parity of  $|\mathcal{Q}|$ . When Spoiler removes a pebble and places it outside the graph, two cases arise. If  $CC_S(F)$  remains unchanged, Duplicator again takes no action. However, if the removal of the pebble causes multiple connected components  $\mathcal{P}_1, \dots, \mathcal{P}_k$  to merge into a larger component  $\mathcal{P} = \bigcup_{i=1}^k \mathcal{P}_i$ , Duplicator updates  $\mathcal{Q}$  by either removing the smaller components, i.e.,  $\tilde{\mathcal{Q}} = \mathcal{Q} \setminus \{\mathcal{P}_1, \dots, \mathcal{P}_k\}$ , or adding the merged component, i.e.,  $\tilde{\mathcal{Q}} = (\mathcal{Q} \setminus \{\mathcal{P}_1, \dots, \mathcal{P}_k\}) \cup \mathcal{P}$ , depending on which option preserves  $|\tilde{\mathcal{Q}}| \equiv 1 \pmod{2}$ . When Spoiler swaps the positions of the two pebbles, the connected components  $CC_S(F)$  do not change, so Duplicator does not modify  $\mathcal{Q}$ .

Spoiler wins the game if, after any round,  $\mathcal{Q}$  contains a connected component that forms a path. Duplicator wins if Spoiler is unable to achieve this outcome after any number of rounds.

**Lemma B.31.** *Given a base graph  $F$ , Spoiler cannot win the simplified pebble game on  $F$  in  $d$  steps iff  $\chi_G^{\text{Spec},(d+1)}(G(F)) = \chi_H^{\text{Spec},(d+1)}(H(F))$ .*

*Proof.* Initially, we introduce a "half-simplified" game as follows: Let  $F = (V_F, E_F)$  be the base graph of a proper Fürer graph. This version of the pebble game is also played on  $F$ , with two pebbles  $u$  and  $v$ . Initially, both pebbles are outside the graph  $F$ .

- First, we describe the rules for the Spoiler. Spoiler maintains a subset  $\mathcal{Q}_1 \subset CC_S(F)$  of connected components, where the set  $\mathcal{S}$  consists of the vertices in  $F$  currently occupied by the pebbles  $u$  and  $v$ . (If pebble  $v$  is outside  $F$ , then  $\mathcal{S}$  contains only the vertex where  $u$  is placed.) Initially, Spoiler places  $u$  on any vertex of  $F$  and leaves  $v$  outside the graph, maintaining  $\mathcal{Q}_1 = \{E_F\}$ . Then, the game proceeds cyclically as follows:
  - Spoiler places  $v$  on any vertex of  $F$ . Two cases arise for maintaining  $\mathcal{Q}_1$ : if  $CC_S(F)$  does not change, Spoiler leaves  $\mathcal{Q}_1$  unchanged. Otherwise, the new pebble may split some connected components into smaller regions. For each original component  $\mathcal{P} \subset E_F$  that splits into  $\mathcal{P}_1, \dots, \mathcal{P}_k$  with  $\bigcup_{i=1}^k \mathcal{P}_i = \mathcal{P}$ , Spoiler updates  $\mathcal{Q}_1$  to  $\tilde{\mathcal{Q}}_1 = (\mathcal{Q}_1 \setminus \mathcal{P}) \cup \{\mathcal{P}_{j_1}, \dots, \mathcal{P}_{j_l}\}$ , where  $j_1, \dots, j_l \in [k]$  and  $|\tilde{\mathcal{Q}}_1| \equiv 0 \pmod{2}$ . This ensures that the parity of  $|\mathcal{Q}_1|$  remains unchanged.
  - Spoiler swaps the positions of  $u$  and  $v$ , leaving  $\mathcal{Q}_1$  unchanged.
  - Spoiler removes  $v$  from the graph, leaving it outside  $F$ . Again, two cases arise for maintaining  $\mathcal{Q}_1$ : if  $CC_S(F)$  does not change, Spoiler does nothing. Otherwise, several connected components  $\mathcal{P}_1, \dots, \mathcal{P}_k$  may merge into a larger component  $\mathcal{P} = \bigcup_{i=1}^k \mathcal{P}_i$ . Spoiler then updates  $\mathcal{Q}_1$  to either  $\tilde{\mathcal{Q}}_1 = \mathcal{Q}_1 \setminus \{\mathcal{P}_1, \dots, \mathcal{P}_k\}$  or  $\tilde{\mathcal{Q}}_1 = (\mathcal{Q}_1 \setminus \{\mathcal{P}_1, \dots, \mathcal{P}_k\}) \cup \mathcal{P}$ , whichever satisfies  $|\tilde{\mathcal{Q}}_1| \equiv 0 \pmod{2}$ .
- Next, we describe the rules for the Duplicator, which are analogous to the Spoiler's rules but with a key difference: Duplicator maintains a subset  $\mathcal{Q}_2 \subset CC_S(F)$  where the parity of  $|\mathcal{Q}_2|$  is always odd. Initially,  $\mathcal{Q}_2 = \{E_F\}$ , and throughout the game, Duplicator performs the following updates:
  - When Spoiler places a pebble, Duplicator updates  $\mathcal{Q}_2$  in the same manner as  $\mathcal{Q}_1$ , but ensuring  $|\tilde{\mathcal{Q}}_2| \equiv 1 \pmod{2}$ .
  - When Spoiler removes a pebble, Duplicator updates  $\mathcal{Q}_2$  as in the previous case, ensuring that the parity of  $|\mathcal{Q}_2|$  remains odd.
  - When Spoiler swaps the pebbles, Duplicator does nothing, as  $CC_S(F)$  remains unchanged.

The result of the game is determined as follows: Suppose that pebbles  $u$  and  $v$  are placed on vertices of  $F$ . Spoiler maintains the subset  $\mathcal{Q}_1$ , and Duplicator maintains  $\mathcal{Q}_2$ . We then construct two twisted Fürer graphs:  $\tilde{G}(F) = \text{twist}(G(F), \tilde{\mathcal{E}})$  and  $\hat{G}(F) = \text{twist}(G(F), \hat{\mathcal{E}})$ , where  $|\tilde{\mathcal{E}}| = |\mathcal{Q}_1|$  and, for each  $\mathcal{P} \in \mathcal{Q}_1$ , we select a single edge  $\tilde{\mathcal{E}} \cap \mathcal{P} = 1$ . Similarly,  $|\hat{\mathcal{E}}| = |\mathcal{Q}_2|$ , and for

each  $\mathcal{P} \in \mathcal{Q}_2$ , we select a single edge  $\hat{\mathcal{E}} \cap \mathcal{P} = 1$ . Spoiler wins if the walk vector satisfies  $\omega_{\hat{G}(F)}^*((u, \emptyset), (v, \emptyset)) \neq \omega_{G(F)}^*((u, \emptyset), (v, \emptyset))$ , meaning that there exists an  $n$ -walk in  $\hat{G}(F)$  from  $(u, \emptyset)$  to  $(v, \emptyset)$  that differs from the corresponding  $n$ -walk in  $G(F)$ . Following a similar analysis to Theorem 17 in Zhang et al. (2023a), we can show that the "half-simplified" pebble game is equivalent to the original pebble game. Specifically, the Spoiler can win in  $d$  steps in the original pebble game if and only if the Spoiler can win in  $d$  steps in the half-simplified pebble game. Therefore, it remains to prove the equivalence between the half-simplified and the original pebble games. We refer to the pebble game described in this section as the half-simplified game. Let  $F = (\mathcal{V}_F, \mathcal{E}_F)$  be the base graph and  $G(F)$  the corresponding F\"urer graph. Furthermore, we denote the game states in the simplified game by  $(\mathcal{S}, \mathcal{Q})$ , where  $\mathcal{S}$ , which can be either  $(u, v)$  or  $(u)$ , represents the pebble positions on the base graph  $F$ , and  $\mathcal{Q}$  denotes the set of connected components that the Duplicator is currently maintaining. Similarly, we define the game state in the half-simplified game as  $(\mathcal{S}, \mathcal{Q}_1, \mathcal{Q}_2)$ , where  $\mathcal{S}$  represents the placement of the pebbles on  $F$ , and  $\mathcal{Q}_1$  and  $\mathcal{Q}_2$  denote the sets of connected components maintained by the Spoiler and Duplicator, respectively. We now proceed to prove the following claim: If the Duplicator can win the half-simplified game, then they have a strategy to ensure that, for every game state  $((u, v), \mathcal{Q}_1, \mathcal{Q}_2)$ , the symmetric difference  $\mathcal{Q}_1 \Delta \mathcal{Q}_2$  contains no path connecting  $u$  and  $v$  in the base graph  $F$ .

If the Duplicator can win the game, then for every game state  $((u, v), \mathcal{Q}_1, \mathcal{Q}_2)$ , we can select an edge from each connected component in  $\mathcal{Q}_1$  to form an edge set  $\mathcal{E}_1$ , and similarly, select an edge from each connected component in  $\mathcal{Q}_2$  to form an edge set  $\mathcal{E}_2$ . Let  $G_1(F) = \text{twist}(G(F), \mathcal{E}_1)$  and  $G_2(F) = \text{twist}(G(F), \mathcal{E}_2)$ . Since the Duplicator can win the game, it follows that  $\omega_{G_1(F)}^*((u, \emptyset), (v, \emptyset)) = \omega_{G_2(F)}^*((u, \emptyset), (v, \emptyset))$ . Consequently, for  $n < |V_{G_1(F)}|$ , we have  $\omega_{G_1(F)}^n((u, \emptyset), (v, \emptyset)) = \omega_{G_2(F)}^n((u, \emptyset), (v, \emptyset))$ , meaning that the number of  $n$ -walks connecting  $(u, \emptyset)$  and  $(v, \emptyset)$  is equal. According to Theorem B.28, the number of paths of length  $n$  connecting  $u$  and  $v$  in  $\mathcal{Q}_1$  and  $\mathcal{Q}_2$  is equal for all  $n \leq |V_F|$ . To construct a winning strategy for the Duplicator, we modify it as follows: for every game state  $((u, v), \mathcal{Q}_1, \mathcal{Q}_2)$ , ensure that  $\mathcal{Q}_1 \Delta \mathcal{Q}_2$  contains no path connecting  $u$  and  $v$  in  $F$ . If there exists a game state  $((u, v), \mathcal{Q}_1, \mathcal{Q}_2)$  such that  $\mathcal{Q}_1 \Delta \mathcal{Q}_2$  contains paths connecting  $u$  and  $v$ , then for every  $n \leq |V_F|$ , if  $\mathcal{Q}_1 \Delta \mathcal{Q}_2$  contains an  $n$ -length path, the number of  $n$ -length paths in  $\mathcal{Q}_1$  and  $\mathcal{Q}_2$  must be equal. Therefore, when the Spoiler places pebble  $v$  on the base graph  $F$ , the Duplicator can modify their strategy to choose exactly the same  $n$ -paths as the Spoiler. This modification does not affect previous or future stages of the game due to symmetry principles, as the Spoiler can still apply their strategy in the remaining part of the game. However, this adjustment strictly eliminates any game state where  $\mathcal{Q}_1 \Delta \mathcal{Q}_2$  contains paths connecting  $u$  and  $v$  in  $F$ . By recursively applying this modification from the initial state, we can construct a strategy for the Duplicator such that, for every game state  $((u, v), \mathcal{Q}_1, \mathcal{Q}_2)$ ,  $\mathcal{Q}_1 \Delta \mathcal{Q}_2$  contains no path connecting  $u$  and  $v$  in  $F$ .

With the result established above, we are now in a position to complete the proof of Lemma 3.20. We will address the two directions of the lemma separately:

1. First, we show that if the Duplicator can win the half-simplified pebble game, then they can also win the simplified pebble game. Let  $G^S$  denote the game state graph of the half-simplified pebble game, in which the Duplicator has a winning strategy. We can straightforwardly derive the game state graph of the simplified pebble game, denoted by  $\tilde{G}^S$ , by replacing each game state  $(u, \mathcal{Q}_1, \mathcal{Q}_2)$  with  $(u, \mathcal{Q}_1 \Delta \mathcal{Q}_2)$ , and each game state  $((u, v), \mathcal{Q}_1, \mathcal{Q}_2)$  with  $((u, v), \mathcal{Q}_1 \Delta \mathcal{Q}_2)$ . Without loss of generality, we can assume that in  $G^S$ , for every game state  $((u, v), \mathcal{Q}_1, \mathcal{Q}_2)$ , there exists no path connecting  $u$  and  $v$  in  $\mathcal{Q}_1 \Delta \mathcal{Q}_2$ . Thus,  $\tilde{G}^S$  is a valid game state graph with legal transitions for the simplified pebble game.
2. Next, we show that if the Duplicator can win the simplified pebble game, they can also win the half-simplified pebble game. Suppose the Duplicator has a winning strategy in the simplified pebble game, and let  $\tilde{G}^S$  be the corresponding game state graph. The Duplicator will recursively apply the following strategy in the half-simplified pebble game:
  - (a) For a game state  $(u, \mathcal{Q}_1, \mathcal{Q}_2)$  in the half-simplified game, we consider the game state  $(u, \mathcal{Q}_1 \Delta \mathcal{Q}_2)$ . If the Spoiler places a pebble on vertex  $v$  of the base graph  $F$  and selects the connected component set  $\tilde{\mathcal{Q}}_1$ , then the Duplicator will select the connected component

set  $\tilde{Q}_2$  such that the transition from  $(u, Q_1 \Delta Q_2)$  to  $((u, v), \tilde{Q}_1 \Delta \tilde{Q}_2)$  is a legal move on the game state graph  $\tilde{G}^S$ .

- (b) Similarly, for a game state  $((u, v), Q_1, Q_2)$  in the half-simplified game, we consider the game state  $((u, v), Q_1 \Delta Q_2)$ . If the Spoiler selects the connected component set  $\tilde{Q}_1$  after swapping the pebbles on  $u$  and  $v$  and removing the pebble from  $u$ , then the Duplicator will choose the connected component set  $\tilde{Q}_2$  such that the transition from  $((u, v), Q_1 \Delta Q_2)$  to  $(u, \tilde{Q}_1 \Delta \tilde{Q}_2)$  is a legal move on the game state graph  $\tilde{G}^S$ .

From the construction of this strategy, it is evident that every game state  $(S, Q_1, Q_2)$  in the half-simplified pebble game corresponds to a game state  $(S, Q_1 \Delta Q_2)$  in the game state graph  $G^S$ . Therefore, the strategy outlined above is well-defined.

By combining the two arguments above, we conclude that the Duplicator can win the simplified pebble game in  $d$  steps if and only if they can win the original pebble game in  $d$  steps.

□

Thus, we finish the proof of Lemma 3.20 in the main body of our paper.

## B.6 STEP 5: PROVING THE MAXIMALITY OF HOMOMORPHISM EXPRESSIVITY

Before presenting the proof, we redefine the concept of the game state graph for clarity in the technical exposition. Notably, there is a slight difference between the definition of the game state graph here and the one in the previous section: we only consider game states with a single pebble in the game state graph.

**Definition B.32.** We define the game state  $(u, Q)$  as in the previous section, where  $u \in V_F$  represents the position of the pebble, and  $Q$  is the connected component maintained by the Duplicator. The game state graph is formed by all game states  $(u, Q)$ . There is an edge from  $(u, Q)$  to  $(\tilde{u}, \tilde{Q})$  if there exists a game transition from  $(u, Q)$  to  $((\hat{u}, \hat{v}), \hat{Q})$ , followed by a transition from  $((\hat{u}, \hat{v}), \hat{Q})$  to  $(\tilde{u}, \tilde{Q})$ , for some connected component set  $\hat{Q} \subset E_F$  and vertex  $\hat{v} \in V_F$ .

**Definition B.33.** A game state  $(u, Q)$  is called a terminal game state if there is a transition from  $(u, Q)$  to a game state  $((u, \tilde{v}), \tilde{Q})$  for some connected component set  $\tilde{Q} \subset E_F$  and vertex  $\tilde{v} \in V_F$ , such that  $\tilde{Q}$  consists only of a single path. In this case, the game state  $(u, Q)$  is called a terminal game state. It is straightforward to see that the Spoiler can win in the terminal state.

**Definition B.34.** Given a game state graph  $G^S$ , a state  $(u, Q)$  is termed "contracted" if, for any transition  $(u, Q) \rightarrow (u', Q') \in E_{G^S}$ , it holds that  $Q' \subset Q$ . The state is called "strictly contracted" if, for any transition  $(u, Q) \rightarrow (u', Q') \in E_{G^S}$ , it holds that  $Q' \subsetneq Q$ .

**Definition B.35.** A game state  $(u, Q)$  is defined as "unreachable" if any path starting from the initial state  $(\emptyset, E_F)$  and ending at  $(u, Q)$  passes through a terminal state.

We do not need to consider unreachable states since the Spoiler always wins before reaching them.

**Lemma B.36.** For any graph  $F$ , if the Spoiler can win the pebble game on  $F$ , then there exists a game state graph  $G^S$  corresponding to a winning strategy for the Spoiler such that all reachable and non-terminal states are strictly contracted.

*Proof.* 1. First, we prove that there exists a strategy for the Spoiler such that every reachable and non-terminal state is contracted. Since the Spoiler can win the pebble game, they can win at any reachable state  $(u, Q)$ . Consider any strategy where  $(u, Q)$  is not contracted. Note that the game state graph induced by all reachable states is a Directed Acyclic Graph (DAG), so we can choose a state  $(u, Q)$  such that no path from the initial state  $(\emptyset, \{E_F\})$  to  $(u, Q)$  passes through any intermediate state that is not contracted. Next, we construct a new strategy to make the state  $(u, Q)$  unreachable. We clearly have  $u \neq \emptyset$ . Without loss of generality, assume there is a transition  $(u, Q) \rightarrow (u', Q')$  such that  $Q' \not\subset Q$ . Let  $(u_0, Q_0), (u_1, Q_1), \dots, (u_T, Q_T)$  be any path from the initial state  $(\emptyset, \{E_F\})$  to  $(u, Q)$ . We modify the strategy as follows: at state  $(u_{T-1}, Q_{T-1})$ , the Spoiler places the pebble  $p_v$  on  $u'$ , swaps the pebbles at  $u$  and  $v$ , and then removes  $p_v$  from the graph. This process can be repeated for every path from the initial state  $(\emptyset, E_F)$  to the state  $(u, Q)$ . In the new strategy,  $(u, Q)$  will become unreachable. However,

1782 the state  $(u_{T-1}, \mathcal{Q}_{T-1})$  may now violate the contraction condition. In this case, we recursively  
 1783 apply the above procedure to  $(u_{T-1}, \mathcal{Q}_{T-1})$ . Note that this process will terminate after a finite  
 1784 number of steps, as the length of the path from the initial state to  $(u_{T-1}, \mathcal{Q}_{T-1})$  is strictly  
 1785 shorter than the path to  $(u, \mathcal{Q})$ .

1786 2. Next, we prove that every reachable and non-terminal state can be strictly contracted. Suppose,  
 1787 for contradiction, that  $(u, \mathcal{Q})$  is reachable and non-terminal, but not strictly contracted. Then  
 1788 there exists a transition  $((u, \mathcal{Q}) \rightarrow (u', \mathcal{Q}')) \in E_{G^S}$ . Since  $u$  is at the boundary of all connected  
 1789 components, we have  $u = u'$ . This implies that the game state graph is not acyclic, which  
 1790 contradicts the assumption that it is a DAG.

1791 Combining the above two points, we conclude that for any given graph  $F$ , if the Spoiler can win the  
 1792 pebble game on  $F$ , then there exists a game state graph  $G^S$  corresponding to a winning strategy for  
 1793 the Spoiler such that every reachable and non-terminal state is strictly contracted.  $\square$   
 1794

1795 **Lemma B.37.** *Given any connected graph  $F$ , if the Spoiler can win the pebble game on  $F$ , then*  
 1796  *$F$  is a parallel tree. Specifically, there exists a tree skeleton  $T^r = (V_{T^r}, E_{T^r}, \beta_{T^r}, \gamma_{T^r})$  such that*  
 1797  *$(F, T^r) \in \mathcal{S}^{\text{pt}}$ .*

1798  
 1799 *Proof.* Let  $G^S$  be the game state graph satisfying Lemma B.36. For each game state  
 1800  $s$ , denote  $\text{next}_{G^S}(s)$  as the set of states  $s'$  such that  $(s, s')$  is a transition in  $G^S$  and  
 1801  $s'$  contains only a single component, i.e.,  $s'$  has the form  $(u, \{P\})$ . By definition,  
 1802  $\text{next}_{G^S}(\emptyset, \{E_F\}) = \{(u, Q_1), \dots, (u, Q_m)\}$  for some  $u \in V_F$ , where  $Q_1, \dots, Q_m$  is the  
 1803 finest partition of  $\text{CC}_F(\{u\})$ .  
 1804

1805 The tree  $T^r$  will be recursively constructed as follows. First, create the tree root  $r$  with  
 1806  $\beta_T(r) = u$ . As will be explained later, the root node will be associated with the set of states  
 1807  $S(r) := \text{next}_{G^S}(\emptyset, \{E_F\})$ . We then proceed with the following procedure:  
 1808

1809 Let  $t$  be a leaf node in the current tree associated with a non-empty set of game states  $S(t)$   
 1810 such that  $|\cup_{(u, \{P\}) \in S(t)} P| > 1$ . For each state  $(u, \{P\}) \in S(t)$ , create a new node  $\tilde{t}$  and set its  
 1811 parent to be  $t$ . Pick any state  $(v, \{P'\}) \in \text{next}_{G^S}(u, \{P\})$ , and set  $\beta_T(\tilde{t}) = v$ . Then, node  $\tilde{t}$  will be  
 1812 associated with the set of states  $S(\tilde{t}) = \{(v, \{P'\}) : (v, \{P'\}) \in \text{next}_{G^S}(u, \{P\})\}$ .  
 1813

1814 We now prove that  $T^r$  is indeed a valid tree skeleton for  $F$ . By definition of a parallel tree,  
 1815 when constructing  $T^r$  and defining the label function  $\beta_T : V_{T^r} \rightarrow V_F$ , we can naturally define the  
 1816 label function for edges  $\gamma_T : E_{T^r} \rightarrow 2^{E_F}$ . For any edge  $(t_1, t_2) \in E_{T^r}$ , there exist only paths  
 1817 connecting  $\beta_T(t_1)$  and  $\beta_T(t_2)$  in  $F$ . Therefore, the image of  $(t_1, t_2)$  is naturally defined as the set  
 1818 of paths connecting  $\beta_T(t_1)$  and  $\beta_T(t_2)$ . Since  $\beta_T$  is already defined for the nodes of  $T^r$ , it remains  
 1819 to prove that for every edge  $(t_1, t_2) \in E_{T^r}$ , there exist only paths connecting  $\beta_T(t_1)$  and  $\beta_T(t_2)$  in  
 1820  $F$ .  
 1821

1821 We revisit the construction of  $T^r$ . Let  $t$  be a leaf node associated with the game states  $S(t)$ .  
 1822 For each game state  $(u, \{P\}) \in S(t)$ , create a new node  $\tilde{t}$  and set its parent to  $t$ . Pick any state  
 1823  $(v, \{P'\}) \in \text{next}_{G^S}(u, \{P\})$ , and set  $\beta_T(\tilde{t}) = v$ . Since  $(v, \{P'\}) \in \text{next}_{G^S}(u, \{P\})$ , the transition  
 1824  $((u, \{P\}), (v, \{P'\}))$  is a legal move in the pebble game.

1825 Moreover, since we assume that  $G^S$  satisfies Lemma B.36, we can conclude that the game state  
 1826  $(u, \{P\})$  is strictly contracted. In other words,  $P' \subset P$ . This implies that when the Spoiler places  
 1827 the pebble  $p_v$  on vertex  $v \in V_F$ , the Duplicator can only choose a strictly contracted connected  
 1828 component set. Hence, we deduce that there are only paths connecting  $u$  and  $v$ . Consequently, there  
 1829 exist only paths connecting  $\beta_T(t)$  and  $\beta_T(\tilde{t})$ .

1830 By recursively applying this analysis throughout the construction of  $T^r$ , we conclude that for every  
 1831 edge  $(t_1, t_2) \in E_{T^r}$ , there exist only paths connecting  $\beta_T(t_1)$  and  $\beta_T(t_2)$  in graph  $F$ .  $\square$   
 1832

1833 We now prove finite-iteration version of Lemma B.37 as follows:

1834 **Lemma B.38.** *Given any base graph  $F$ , Spoiler can win the simplified pebble game on  $F$  in  $d$  steps*  
 1835 *iff there exists a parallel tree skeleton  $T^r$  of  $F$  such that  $T^r$  has depth at most  $d + 1$ .*

1836 *Proof.* Initially, it is evident that if  $F$  is a parallel tree with a tree skeleton of depth at most  $d + 1$ ,  
 1837 then the Spoiler has a winning strategy in  $d$  steps. Therefore, we are left to consider the converse  
 1838 direction of the lemma. Now, consider the case where, for a base graph  $F$ , the Spoiler has a winning  
 1839 strategy in  $d$  steps. According to the analysis in Lemma B.36, if the Spoiler has a winning strategy  
 1840 in  $d$  steps, then he can guarantee that all reachable non-terminal states in the game state graph  $G^S$   
 1841 are strictly contracted. We will prove this statement by induction. The statement trivially holds for  
 1842  $d = 1$ . Assume that if the Spoiler has a winning strategy in  $d - 1$  steps, then the base graph is a  
 1843 parallel tree with a tree skeleton of depth at most  $d$ . Now, we consider the case where the Spoiler  
 1844 can win in  $d$  steps.

1845 By Lemma B.37, the Spoiler can win the game on  $F$ , implying that  $F$  is a parallel tree. Let  $T^r$  be  
 1846 the tree skeleton of  $F$ . At the beginning of the game, we first consider the case where the Spoiler  
 1847 places a pebble on a vertex  $u$  such that  $u \notin \{v : \exists t \in V_T, \beta_T(t) = v\}$ . We assume that the  
 1848 Duplicator selects connected component  $P$  (since  $F$  is a parallel tree, the Duplicator can only select  
 1849 one connected component in this case). Assume further that there exist  $t, t' \in V_T$  such that  $u$  is on  
 1850 a path connecting  $\beta_T(t)$  and  $\beta_T(t')$ . We now consider two separate cases:

- 1851 • If there is more than one path connecting  $\beta_T(t)$  and  $\beta_T(t')$  in  $F$ , i.e.,  $|\gamma_T(t, t')| > 1$ , then  
 1852 placing the pebble on  $u$  does not split  $F$ , and it remains as one connected component. In this  
 1853 case, we can directly eliminate  $(u, P)$  from the game state graph, and the remaining game state  
 1854 graph still represents a winning strategy for the Spoiler.
- 1855 • If there is only one path connecting  $\beta_T(t)$  and  $\beta_T(t')$  in  $F$ , i.e.,  $|\gamma_T(t, t')| = 1$ , then placing the  
 1856 pebble on  $u$  splits the base graph  $F$  into two connected components. In this case, we replace the  
 1857 game state  $(u, \{P\})$  in the game state graph with  $\{u', \{P'\}\}$ , where  $u' \in \{\beta_T(t), \beta_T(t')\}$  and  
 1858  $P \subset P'$ .

1859 Following this discussion, we only need to consider the case where, at the beginning of the game,  
 1860 the Spoiler places the pebble on a vertex  $u \in V_F$  such that there exists  $t \in V_T$  and  $u = \beta_T(t)$ .  
 1861 Without loss of generality, assume  $u = \beta_T(r)$ , and the children of  $r$  are  $\{t_1, \dots, t_n\}$ . Further,  
 1862 assume that among all subtrees induced by  $t_1, t_2, \dots, t_n$ , the subtree induced by  $t_1 \in V_T$  has the  
 1863 greatest depth. We now consider the case where the Duplicator picks the connected component  
 1864 formed by the subtree induced by  $t_1$  and the path in  $\gamma_T(r, t_1)$ . If the Spoiler must ensure that the  
 1865 subsequent game state is strictly contracted, he must place the pebble on  $t_1$ . The remaining game  
 1866 now reduces to a game played on the graph induced by the subtree formed by all descendants of  $t_1$ .  
 1867 By the induction hypothesis, the subtree induced by  $t_1$  has depth at most  $d$ . Thus,  $T^r$  has depth at  
 1868 most  $d + 1$ .  $\square$

1869 We now prove Lemma 3.21 from the main paper.

1870 **Lemma B.39.** For any  $F \notin \mathcal{F}^{\text{Spec},(d)}$ , the Spoiler cannot win the simplified pebble game on  $F$  in  
 1871  $d - 1$  steps. Consequently,  $\chi_G^{\text{Spec},(d)}(G(F)) = \chi_H^{\text{Spec},(d)}(H(F))$ .

1872 *Proof.* By Lemma B.38, since  $F \notin \mathcal{F}^{\text{Spec},(d)}$ , the Spoiler cannot win the simplified pebble game on  
 1873 the base graph  $F$ . Thus, by Lemma 3.20, we conclude that  $\chi_G^{\text{Spec},(d)}(G(F)) = \chi_H^{\text{Spec},(d)}(H(F))$ .  $\square$

1874 Combining all the results from steps 1 through 5, we now conclude the proof of our main theorem.

1875 **Theorem B.40.** The homomorphism expressivity of spectral invariant GNNs with  $d$  iterations can  
 1876 be characterized as follows:

$$1877 \mathcal{F}^{\text{Spec},(d)} = \{F \mid F \text{ has parallel tree depth at most } d\}.$$

1878 Specifically, the following properties hold:

- 1879 • For graphs  $G$  and  $H$ ,  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$  if and only if, for all graphs  $F$  with parallel  
 1880 tree depth at most  $d$ ,  $\text{hom}(F, G) = \text{hom}(F, H)$ .
- 1881 •  $\mathcal{F}^{\text{Spec},(d)}$  is maximal; that is, for any graph  $F \notin \mathcal{F}^{\text{Spec},(d)}$ , there exist graphs  $G$  and  $H$  such  
 1882 that  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$  and  $\text{hom}(F, G) \neq \text{hom}(F, H)$ .

*Proof.* By Theorem B.20 and Corollary B.10, we obtain that for graphs  $G$  and  $H$ ,  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$  if and only if, for all graphs  $F$  with parallel tree depth at most  $d$ ,  $\text{hom}(F, G) = \text{hom}(F, H)$ . Furthermore, by Lemma 3.21, there exist counterexamples  $G$  and  $H$  for any  $F \notin \mathcal{F}^{\text{Spec},(d)}$  such that  $\chi_G^{\text{Spec},(d)}(G) = \chi_H^{\text{Spec},(d)}(H)$  and  $\text{hom}(F, G) \neq \text{hom}(F, H)$ . Thus, we conclude the proof of the main theorem.  $\square$

## C PROOF OF THEOREM 3.10

In this section, we provide the proof of Theorem 3.10 from the main paper.

**Theorem C.1.** *The homomorphism expressivity of graph spectra is the set of all cycles  $C_n$  ( $n \geq 3$ ) plus paths  $P_1$  and  $P_2$ , i.e.,  $\{C_n | n \geq 3\} \cup \{P_1, P_2\}$ .*

*Proof.* We separately prove that the set of all cycles satisfies the two conditions of homomorphism expressivity. For a graph  $G$ , we denote  $\mathbf{A}_G \in \mathbb{R}^{|V_G| \times |V_G|}$  as the adjacency matrix of  $G$ , and  $\text{Spec}(G) = \{\lambda_{G,1}, \lambda_{G,2}, \dots, \lambda_{G,|V_G|}\}$  as the spectrum of  $G$ .

- We first prove that for any two graphs  $G$  and  $H$ , their spectra are identical if and only if for every  $F \in \{C_n | n \geq 3\} \cup \{P_1, P_2\}$ ,  $\text{hom}(F, G) = \text{hom}(F, H)$ . Let  $C_n$  denote a cycle with  $n$  vertices. For any graph  $G$ , we have  $\text{hom}(C_n, G) = \text{tr}(\mathbf{A}_G^n)$  for all  $n \in \mathbb{N}_{\geq 3}$ , and for  $n = 2$ , we denote  $C_2 = P_2$ . Moreover, by a basic result from linear algebra, we further obtain:

$$\text{hom}(C_n, G) = \text{tr}(\mathbf{A}_G^n) = \lambda_{G,1}^n + \lambda_{G,2}^n + \dots + \lambda_{G,|V_G|}^n.$$

Therefore, if  $\text{hom}(C_n, G) = \text{hom}(C_n, H)$  for all  $n \in \mathbb{N}^+$ , then we have:

$$\lambda_{G,1}^n + \lambda_{G,2}^n + \dots + \lambda_{G,|V_G|}^n = \lambda_{H,1}^n + \lambda_{H,2}^n + \dots + \lambda_{H,|V_H|}^n, \quad \text{for all } n \in \mathbb{N}^+.$$

Thus,  $\text{Spec}(G) = \text{Spec}(H)$ . Conversely, if we are given that  $\text{Spec}(G) = \text{Spec}(H)$ , then:

$$\text{hom}(C_n, G) = \text{tr}(\mathbf{A}_G^n) = \text{tr}(\mathbf{A}_H^n) = \text{hom}(C_n, H), \quad \text{for all } n \in \mathbb{N}^+.$$

Therefore, we have proven that for any two graphs  $G$  and  $H$ , their spectra are identical if and only if for every  $F \in \{C_n | n \geq 3\} \cup \{P_1, P_2\}$ ,  $\text{hom}(F, G) = \text{hom}(F, H)$ .

- We now prove that for any graph  $F$  that is not a cycle nor a path, there exists a pair of graphs  $G$  and  $H$  such that their spectra are identical, but  $\text{hom}(F, G) \neq \text{hom}(F, H)$ . Specifically, we show that for any graph  $F$  that is not a cycle,  $\text{Spec}(G(F)) = \text{Spec}(H(F))$  holds, where  $G(F)$  and  $H(F)$  denote the pair of Furer graphs constructed with  $F$  as the base graph.

If  $F$  is not nor a path, then there exist vertices  $x, y \in V_F$  such that the degree of  $x$  is not 2. We then consider the Furer graph  $G(F)$  and the twisted Furer graph  $H(F) = \text{twist}(G(F), \{x, y\})$ . According to Theorem B.28, for vertices  $v, x_2, \dots, x_n \in V_F$  and  $\mathcal{V} \subset V_F$ , the number of  $n$ -walks passing through  $(v, \mathcal{V}), \text{Meta}(x_2), \dots, \text{Meta}(x_n), (v, \mathcal{V})$  sequentially in  $G(F)$  and  $H(F)$  is unequal. Specifically,  $x_2, \dots, x_n$  satisfy the following properties:

1.  $(v, x_2), (x_2, x_3), \dots, (x_{n-1}, x_n), (x_n, v) \in E_F$ .
2. The degree of  $x_2, \dots, x_n$  is 2 in the base graph  $F$ .
3. Let  $x_1 = x_{n+1} = v$ , then:

$$|\{\{x_i, x_{i+1}\}, i = 1, 2, \dots, n\} \cap \{\{x, y\}\}| \equiv 1 \pmod{2}.$$

From this, we deduce that  $v = x$ , and we have:

$$\sum_{(v, \mathcal{V}') \in \text{Meta}(v)} c_{G(F)}^n((v, \mathcal{V}'), x_2, \dots, x_n) = \sum_{(v, \mathcal{V}') \in \text{Meta}(v)} c_{H(F)}^n((v, \mathcal{V}'), x_2, \dots, x_n), \quad (6)$$

where for any vertex  $(v, \mathcal{V}') \in \text{Meta}(v)$ , we use notations  $c_{G(F)}^n((v, \mathcal{V}'), x_2, \dots, x_n)$  and  $c_{H(F)}^n((v, \mathcal{V}'), x_2, \dots, x_n)$  to denote the number of  $n$ -walks passing through  $(v, \mathcal{V}'), \text{Meta}(x_2), \dots, \text{Meta}(x_n), (v, \mathcal{V}')$  in  $G(F)$  and  $H(F)$ , respectively. If  $x_2, \dots, x_n$  do not satisfy the above properties, then for all  $(v, \mathcal{V}') \in \text{Meta}(v)$ , the number of  $n$ -walks passing through  $(v, \mathcal{V}'), \text{Meta}(x_2), \dots, \text{Meta}(x_n), (v, \mathcal{V}')$  in  $G(F)$  and  $H(F)$  is equal. Thus, equation 6

(a) Counterexample for Theorem 3.10 (Graph  $G$ ) (b) Counterexample for Theorem 3.10 (Graph  $H$ )

Figure 5: Counterexample for Theorem 3.10

holds for all  $v, x_2, \dots, x_n \in V_F$ . Consequently, we observe the following property in terms of walk counts:

$$\sum_{(v, \mathcal{V}') \in \text{Meta}(v)} \omega_{G(F)}^n((v, \mathcal{V}'), (v, \mathcal{V}')) = \sum_{(v, \mathcal{V}') \in \text{Meta}(v)} \omega_{H(F)}^n((v, \mathcal{V}'), (v, \mathcal{V}')),$$

where  $\omega_{G(F)}^n((v, \mathcal{V}'), (v, \mathcal{V}'))$  and  $\omega_{H(F)}^n((v, \mathcal{V}'), (v, \mathcal{V}'))$  denote the number of  $n$ -walks starting and ending at  $(v, \mathcal{V}')$  in  $G(F)$  and  $H(F)$ , respectively. This holds for all  $n \in \mathbb{N}^+$  and all  $(v, \mathcal{V}') \in \text{Meta}(v)$ . Thus, we conclude that  $\text{tr}(\mathbf{A}_{G(F)}^n) = \text{tr}(\mathbf{A}_{H(F)}^n)$  for all  $n \in \mathbb{N}$ . By a basic result from linear algebra, this implies that  $\text{Spec}(G(F)) = \text{Spec}(H(F))$ . However, since  $\text{hom}(F, G(F)) \neq \text{hom}(F, H(F))$ , we have proven that for any graph  $F$  that is not a cycle, there exists a pair of graphs  $G$  and  $H$  such that their spectra are identical, but  $\text{hom}(F, G) \neq \text{hom}(F, H)$ .

- We now prove that for any path  $F$  of length at least 2, there exist graphs  $G$  and  $H$  such that  $\text{hom}(F, G) = \text{hom}(F, H)$ . A pair of counterexamples is provided in Figure 5. Initially, we observe that the two graphs are cospectral. Furthermore, for any path  $P$  of length  $k$  ( $k \geq 2$ ),  $\text{hom}(F, G) = 4 \cdot 2^k + 2$ . For the graph  $H$ , let the number of  $k$ -walks starting from the vertex with degree 3 be denoted as  $a_k$ . We then have the following recurrence relation:

$$a_k = a_{k-1} + 2 \cdot a_{k-2}, \quad a_0 = 1, \quad a_1 = 3.$$

From this relationship, we can deduce that:

$$\begin{aligned} a_{2k+1} &= 2^{2k+1} - 2^{2k+1} + \dots + 2^2 - a_0 = 1 + 2 \cdot (1 + 4 + \dots + 2^{2k}) = \frac{1}{3} (2^{2k+3} + 1), \\ a_{2k} &= 2^{2k+2} - \frac{1}{3} (2^{2k+3} + 1) = \frac{1}{3} (2^{2k+2} - 1). \end{aligned}$$

Therefore, the total number of homomorphisms from a path of length  $2k + 1$  to  $H$  is given by:

$$\begin{aligned} \text{hom}(P_{2k+2}, H) &= 4 \cdot a_{2k} + 2 \cdot a_{2k+1} \\ &= \frac{1}{3} (2 \cdot 2^{2k+3} - 4) + \frac{1}{3} (2 \cdot 2^{2k+3} + 2) + 3 \\ &= \frac{1}{3} (4 \cdot 2^{2k+3} - 2). \end{aligned}$$

Similarly, the total number of homomorphisms from a path of length  $2k + 2$  to  $H$  is:

$$\begin{aligned} \text{hom}(P_{2k+2}, H) &= 4 \cdot a_{2k+1} + 2 \cdot a_{2k+2} \\ &= \frac{4}{3} (2^{2k+3} + 1) + \frac{2}{3} (4 \cdot 2^{2k+5} - 2) \\ &= 3 \cdot 2^{2k+5}. \end{aligned}$$

Thus, for all  $k \geq 3$ , we conclude that:

$$\text{hom}(P_k, G) \neq \text{hom}(P_k, H), \quad \text{for all } k \geq 3.$$

Combining the previous three results, we have proven that homomorphic expressivity is  $\{C_n | n \geq 3\} \cup \{P_1, P_2\}$ .  $\square$

## D EXPERIMENTAL DETAILS

In this section, we provide details on the experiments in Section 4. For dataset setup and training parameters, we follow Zhang et al. (2024a). We also use exactly the same model architecture for MPNN, subgraph GNN, and local 2-GNN as Zhang et al. (2024a) did.

**Model architecture of spectral invariant GNN.** For spectral invariant GNN, we use the same feature initialization and final pooling layer as other models. The feature propagation in each layer is implemented to incorporate the eigenvalues and their projection matrices of the graph. Specifically, suppose  $\{(\lambda, P_\lambda(u, v))\}$  are all eigenvalues and eigenvectors of the input graph,  $h^l(u) \in \mathbb{R}^d$  is the feature vector of node  $u$  in layer  $l$ . Then, the feature in next layer  $l + 1$  is updated according to the following rule:

$$\begin{aligned} h^{(l+1)}(u) &= \text{ReLU}(\text{BN}^{(l)}(\text{MLP}_1^{(l)}((1 + \epsilon^{(l)})h^{(l)}(u) + f^{(l)}(u))), \\ f^{(l)}(u) &= \sum_{v \in \mathcal{V}} \text{ReLU}(h^{(l)}(v) + \sum_{\lambda} \text{MLP}_2^{(l)}(\lambda)P_\lambda(u, v)), \end{aligned} \quad (7)$$

where  $\text{MLP}_{1,2}$  are two-layer feed-forward networks with batch normalization in the hidden layer.

Similar to Zhang et al. (2024a), for graphs with edge features, we maintain a learnable edge embedding,  $g^{(l)}(u, v)$ , for each type of edges, and add them to the aggregation rule  $f^{(l)}(u)$ . The number of layers and hidden dimensions is set to match MPNN, such that all four models have roughly the same, and obey the 500K parameter budget in ZINC, as Zhang et al. (2024a) did.

## E HIGHER ORDER SPECTRAL INVARIANT GNN

### E.1 UPDATE RULE OF HIGHER-ORDER SPECTRAL INVARIANT GNN

A natural update rule for higher-order spectral invariant GNNs is as follows:

**Definition E.1 (Higher-Order Spectral Invariant GNN).** For any  $k \in \mathbb{N}_+$ , the  $k$ -order spectral invariant GNN maintains a color  $\chi_G^{k\text{-Spec}}(\mathbf{u})$  for each vertex  $k$ -tuple  $\mathbf{u} = (u_1, \dots, u_k) \in V_G^k$ . Initially,  $\chi_G^{k\text{-Spec},(0)}(\mathbf{u}) = (\mathcal{P}(u_1, u_2), \dots, \mathcal{P}(u_1, u_k), \dots, \mathcal{P}(u_{k-1}, u_k))$ . In each iteration  $t + 1$ , the color is updated as follows:

$$\begin{aligned} \chi_G^{k\text{-Spec},(t+1)}(\mathbf{u}) &= \text{hash}(\chi_G^{k\text{-Spec},(t)}(\mathbf{u}), \{(\chi_G^{k\text{-Spec},(t)}(v, u_2, \dots, u_k), \mathcal{P}(u_1, v)) : v \in V_G\}, \dots, \\ &\quad \{(\chi_G^{k\text{-Spec},(t)}(u_1, u_2, \dots, u_{k-1}, v), \mathcal{P}(u_k, v)) : v \in V_G\}). \end{aligned}$$

Denote the stable color of vertex tuple  $\mathbf{u} \in V_G^k$  as  $\chi_G^{k\text{-Spec}}(\mathbf{u})$ . The graph representation is defined as  $\chi_G^{k\text{-Spec}}(G) := \{\{\chi_G^{k\text{-Spec}}(\mathbf{u}) : \mathbf{u} \in V_G^k\}\}$ .

### E.2 HOMOMORPHISM EXPRESSIVITY OF HIGHER-ORDER SPECTRAL INVARIANT GNN

To describe the homomorphism expressivity of higher-order spectral invariant GNNs, we draw inspiration from the concept of "strong nested ear decomposition" from Zhang et al. (2024a). For the reader's convenience, we restate the relevant definitions here:

**Definition E.2 ( $k$ -order Ear).** A  $k$ -order ear is a graph  $G$  formed by the union of  $k$  paths  $P_1, \dots, P_k$  (possibly of zero length), along with an edge set  $Q$ , satisfying the following conditions:

- For each path  $P_i$ , let its two endpoints be  $u_i$  (outer endpoint) and  $v_i$  (inner endpoint). All edges in  $Q$  are between inner endpoints, i.e.,  $Q \subset \{\{v_i, v_j\} : 1 \leq i, j \leq k, v_i \neq v_j\}$ .
- Any two distinct paths  $P_i$  and  $P_j$  intersect only at their inner endpoints (if  $v_i = v_j$ ).
- $G$  is a connected graph.

The endpoints of the  $k$ -order ear are the outer endpoints  $u_1, \dots, u_k$ .

**Definition E.3 (Nested Interval).** Let  $G$  and  $H$  be two  $k$ -order ears with  $\text{inner}(G) = \{v_1, \dots, v_k\}$ ,  $\text{outer}(G) = \{u_1, \dots, u_k\}$ , and  $\text{outer}(H) = \{w_1, \dots, w_k\}$ , where each  $\{u_i, v_i\}$  corresponds to the endpoints of a path  $P_i \in \text{path}(G)$ . We say  $H$  is nested on  $G$  if at least one endpoint  $w_i$  of  $H$  ( $i \in [k]$ ) lies on the path  $P_i$ , and all other vertices of  $H$  are not part of  $G$ . The nested interval is defined as the union of the subpaths  $\text{subpath}_{P_i}(w_i, v_i)$  for all  $i \in [k]$  such that  $w_i$  lies on  $P_i$ .

**Definition E.4 ( $k$ -Order Strong Nested Ear Decomposition (NED)).** A  $k$ -order strong NED  $\mathcal{P}$  of a graph  $G$  is a partition of the edge set  $E_G$  into a sequence of edge sets  $Q_1, \dots, Q_m$ , satisfying the following conditions:

- 2052 • Each  $Q_i$  is a  $k$ -order ear.
- 2053
- 2054 • Any two ears  $Q_i$  and  $Q_j$  with indices  $1 \leq i < j \leq c$  do not intersect, where  $c$  is the number of
- 2055 connected components of  $G$ .
- 2056 • For each  $Q_j$  with index  $j > c$ , it is nested on some  $k$ -order ear  $Q_i$  with index  $1 \leq i < j$ .
- 2057 Moreover, except for the endpoints of  $Q_j$  on  $Q_i$ , no other vertices in  $Q_j$  belong to any previous
- 2058 ear  $Q_k$  for  $1 \leq k < i$ .
- 2059 • Denote by  $I(Q_j) \subset Q_i$  the *nested interval* of  $Q_j$  in  $Q_i$ . For all  $Q_j$  and  $Q_k$  with  $c < j < k \leq m$ ,
- 2060 if  $Q_j$  and  $Q_k$  are nested on the same ear, then  $I(Q_j) \subset I(Q_k)$ .

2061 **Definition E.5 (Parallel  $k$ -Order Strong NED).** A graph  $F$  is said to have a parallel  $k$ -order strong

2062 nested ear decomposition (NED) if there exists a graph  $G$  such that  $F$  can be obtained from  $G$  by

2063 replacing each edge  $(u, v) \in E_G$  with a parallel edge that has endpoints  $(u, v)$ .

2064

2065 With the definition of parallel  $k$ -order strong NED, we now state the homomorphism expressivity of

2066  $k$ -spectral invariant GNN as follows:

2067 **Theorem E.6.** *The homomorphism expressivity of a  $k$ -spectral invariant GNN is characterized by*

2068 *the set of all graphs that possess a parallel  $k$ -order strong NED.*

2069

### 2070 E.3 PROOF OF THEOREM E.6

2071

2072 The proof of Theorem E.6 follows a similar structure to the analysis of Theorem 3.3 and Theorem 3.4

2073 in Zhang et al. (2024a). Therefore, we provide only a brief sketch, emphasizing the key differences

2074 between the proof of Theorem E.6 and the previous analyses.

2075

2076 **Lemma E.7.** *For any given graphs  $G$  and  $H$ , we have  $\chi_G^{k\text{-Spec}}(G) = \chi_H^{k\text{-Spec}}(H)$  if and only if,*

2077 *for every graph  $F$  that has a parallel  $k$ -order strong NED,  $\text{hom}(F, G) = \text{hom}(F, H)$ .*

2078

2079 *Proof.* We first define a parallel tree decomposition, which is a variant of the standard tree de-

2080 composition. Given a graph  $G = (V_G, E_G)$ , its tree decomposition is represented as a tree

2081  $T^r = (V_T, E_T, \beta_T, \gamma_T)$ . The label functions  $\beta_T : V_T \rightarrow 2^{V_G}$  and  $\gamma_T : V_T \rightarrow 2^{P_G}$  are defined,

2082 where  $P_G$  denotes the set of paths in  $G$ . The tree  $T = (V_T, E_T, \beta_T, \gamma_T)$  satisfies the following

2083 conditions:

- 2084 1. Each tree node  $t \in V_T$  is associated with a non-empty subset of vertices  $\beta_T(t) \subset V_G$  in  $G$ ,
- 2085 referred to as a bag. Each node  $t \in V_T$  is also associated with a set of paths  $\gamma_T(t)$ , called a
- 2086 sub-bag, which includes paths in  $G$  that begin and end with vertices in  $\beta_T(t)$ . We say that a tree
- 2087 node  $t$  contains a vertex  $u$  if  $u \in \beta_T(t)$ , and contains a path  $p$  if  $p \in \gamma_T(t)$ .
- 2088
- 2089 2. For each path  $(u_1, u_2, \dots, u_n)$  with  $u_i \in V_G$  for  $i \in [n]$ , there exists a tree node  $t \in V_T$  that
- 2090 contains the path, i.e.,  $(u_1, \dots, u_n) \in \gamma_T(t)$ .
- 2091
- 2092 3. For each vertex  $u \in V_G$ , the set of tree nodes  $t$  that contain  $u$ , denoted by  $B_T(u) = \{t \in V_T : u \in \beta_T(t)\}$ ,
- 2093 forms a non-empty connected subtree of  $T$ .
- 2094
- 2095 4. The depth of  $T$  is even, i.e.,  $\max_{t \in V_T} \text{depth}_{T^r}(t)$  is an even number.
- 2096
- 2097 5.  $|\beta_T(t)| = k$  if  $\text{depth}_{T^r}(t)$  is even, and  $|\beta_T(t)| = k + 1$  if  $\text{depth}_{T^r}(t)$  is odd.
- 2098
- 2099 6. For all tree edges  $\{s, t\} \in E_T$ , where  $\text{depth}_{T^r}(s)$  is even and  $\text{depth}_{T^r}(t)$  is odd, we have
- 2100  $\beta_T(s) \subset \beta_T(t)$ .

2101 We refer to  $(G, T^r)$  as a parallel tree-decomposed graph and  $k$  as the width of  $G$ 's parallel tree

2102 decomposition. The set of parallel tree-decomposed graphs with width at most  $k$  is denoted as

2103  $\mathcal{S}^{k\text{-Spec}}$ .

2104 Similar to the low-dimensional case, we define the unfolding tree of a  $k$ -spectral invariant graph

2105 neural network as follows. Given a graph  $G$ , a vertex  $k$ -tuple  $\mathbf{u} = (u_1, \dots, u_k) \in V_G^k$ , and

a non-negative integer  $D$ , the depth- $2D$  spectral  $k$ -spectral invariant tree of  $G$  at  $\mathbf{u}$ , denoted

$(F_G^{k\text{-Spec},(D)}(\mathbf{u}), T_G^{k\text{-Spec},(D)}(\mathbf{u}))$ , is a parallel tree-decomposed graph  $(F, T^r) \in \mathcal{S}^{k\text{-Spec}}$  constructed as follows:

- 2106 1. *Initialization.* Initialize  $F = G[\mathbf{u}]$ , and  $T$  with a root node  $r$  such that  $\beta_T(r) = \{u_1, \dots, u_k\}$ .  
 2107 Define a mapping  $\pi : V_F \rightarrow V_G$  by setting  $\pi(\mathbf{u}) = \mathbf{u}$ . For all  $i, j \in [k]$  with  $i \neq j$  and  
 2108  $r \in [n]$ , if there exists an  $r$ -length walk  $(v_1, \dots, v_r)$  with  $v_1 = u_i$  and  $v_r = u_j$ , we add a path  
 2109  $(w_1, \dots, w_r)$  with  $w_1 = u_i$  and  $w_r = u_j$  to  $F$ , and include  $(w_1, \dots, w_r)$  in the sub-bag  $\gamma_T(r)$ .  
 2110 Moreover, we extend  $\pi$  by setting  $\pi(w_i) = v_i$  for all  $i \in [r]$ .  
 2111 2. *Iterate for  $D$  rounds.* For each leaf node  $t \in T^r$ , execute the following for each  $j \in [n]$ :  
 2112  
 2113 (a) If  $w \notin \{\pi(u_1), \dots, \pi(u_k)\}$ , add a new vertex  $z$  to  $F$  and extend  $\pi$  by setting  $\pi(z) = w$ .  
 2114 Set  $\beta_T(t_w) = \beta_T(t) \cup \{z\}$ . Initialize  $\gamma_T(t_w) = \gamma_T(t)$ , and update  $\gamma_T(t_w)$  by adding paths  
 2115 for all  $i \in [k]$  and  $r$ -length walks  $(w_1, \dots, w_r)$  with  $w_1 = z$  and  $w_r = \pi(u_i)$ .  
 2116 (b) If  $w = \pi(u_r)$  for some  $r \in [k]$ , set  $\beta_T(t_w) = \beta_T(t) \cup \{u_r\}$  without modifying  $F$ .  
 2117 For each  $t_w$ , add a child node  $t'_w$  to  $T^r$ , designate  $t_w$  as its parent, and update  $\beta_T(t'_w)$  based on  
 2118 the following cases:  
 2119 (a) If  $w \notin \{\pi(u_1), \dots, \pi(u_k)\}$ , set  $\beta_T(t'_w) = \{u_1, \dots, u_{j-1}, w, u_{j+1}, \dots, u_k\}$ .  
 2120 (b) If  $w = \pi(u_r)$  for some  $r \in [k]$ , set  $\beta_T(t'_w) = \{u_1, \dots, u_{j-1}, u_r, u_{j+1}, \dots, u_k\}$ .  
 2121 Finally, set  $\gamma_T(t'_w)$  as the set of all paths in  $F$  that connect pairs of vertices in  $\beta_T(t'_w)$ .  
 2122

2123 Following a similar analysis as in the low-dimensional setting, we can first prove that for any  
 2124 two graphs  $G$  and  $H$ ,  $\chi_G^{k\text{-Spec}}(G) = \chi_H^{k\text{-Spec}}(H)$  if and only if  $\text{treeCount}^{k\text{-Spec}}((F, T^r), G) =$   
 2125  $\text{treeCount}^{k\text{-Spec}}((F, T^r), H)$  holds for all  $(F, T^r) \in \mathcal{S}^{k\text{-Spec}}$ . We define

$$2126 \text{treeCount}^{\text{Spec}}((F, T^r), G) \\
 2127 := \left| \left\{ \mathbf{u} \in V_G^k : \exists D \in \mathbb{N}_+ \text{ such that } \left( F_G^{k\text{-Spec}, (D)}(\mathbf{u}), T_G^{k\text{-Spec}, (D)}(\mathbf{u}) \right) \cong (F, T^r) \right\} \right|.$$

2128 With similar arguments as in Theorem 3.4 in Zhang et al. (2024a), we can further prove that for  
 2129 any two graphs  $G$  and  $H$ ,  $\text{treeCount}((F, T^r), G) = \text{treeCount}((F, T^r), H)$  holds for all tree-  
 2130 decomposed graphs  $(F, T^r)$  if and only if  $\text{hom}(F, G) = \text{hom}(F, H)$  holds. We now prove that  
 2131 a graph  $F$  has a parallel tree decomposition with width at most  $k$  if and only if  $F$  admits a parallel  
 2132  $k$ -order strong NED. We prove each direction separately. First, we use induction on the number of  
 2133 vertices in  $F$  to show that for any  $(F, T^r) \in \mathcal{S}^{k\text{-Spec}}$  with  $\beta_T(r) = \{u_1, u_2, \dots, u_k\}$ , there exists  
 2134 a graph  $\tilde{F}$  with a strong NED such that  $\{u_1, \dots, u_k\}$  are the endpoints of the first ear. We can  
 2135 construct  $F$  by replacing edges in  $\tilde{F}$  with parallel edges. For the converse direction, assume that  $F$   
 2136 admits a parallel  $k$ -order strong NED. We aim to prove that there exists a parallel tree decomposition  
 2137  $T^r$  of  $F$  such that  $(F, T^r) \in \mathcal{S}^{k\text{-Spec}}$ . We proceed by induction on the number of vertices and prove  
 2138 a stronger statement. For any connected graph  $F$ , if  $F$  can be constructed by replacing edges in a  
 2139 graph  $\tilde{F}$  with parallel edges, where  $\tilde{F}$  has a  $k$ -order strong NED and the endpoints of the first ear  
 2140 are  $\{u_1, u_2, \dots, u_k\}$ , then there exists a tree decomposition  $T^r$  of  $F$ . This decomposition satisfies  
 2141  $(F, T^r) \in \mathcal{S}^{k\text{-Spec}}$ , and  $\beta_T(r) = \{u_1, u_2, \dots, u_k\}$ . By combining the proofs for both directions,  
 2142 we conclude the proof of the lemma.  $\square$   
 2143

2144 We then prove the maximality of homomorphism expressivity as follows.  
 2145

2146 **Lemma E.8.** *For any connected graph  $F \notin \mathcal{F}^{k\text{-Spec}}$ , there exist graphs  $G$  and  $H$  such that*  
 2147  $\text{hom}(F, G) \neq \text{hom}(F, H)$  *and*  $\chi_G^{k\text{-Spec}}(G) = \chi_H^{k\text{-Spec}}(H)$ .  
 2148

2149 *Proof.* As in the low-dimensional case, we consider a pebble game between two players, the Spoiler  
 2150 and the Duplicator. The game involves a graph  $F$  and several pebbles. Initially, all pebbles are  
 2151 placed outside the graph. During the course of the game, some pebbles are placed on the vertices of  
 2152  $F$ , which divides the edges  $E_F$  into connected components. In each round, the Spoiler updates the  
 2153 position of the pebbles, while the Duplicator manages a subset of connected components, ensuring  
 2154 that the number of selected components is *odd*. There are three main types of operations:

- 2155 1. *Adding a pebble p:* the Spoiler places a pebble  $p$  (which was previously outside the graph)  
 2156 on some vertex of  $F$ . If adding this pebble does not change the connected components, the  
 2157 Duplicator does nothing. Otherwise, some connected component  $P$  is divided into several com-  
 2158 ponents  $P = \bigcup_{i \in [m]} P_i$  for some  $m$ . the Duplicator updates his selection as follows: if  $P$  was  
 2159 selected, he removes  $P$  and adds a subset of  $\{P_1, \dots, P_m\}$ , while ensuring that the total number  
 of selected components remains odd.

- 2160
- 2161 2. *Removing a pebble p*: the Spoiler removes a pebble  $p$  from a vertex. If this action does not alter
- 2162 the connected components, the Duplicator again does nothing. Otherwise, several connected
- 2163 components  $P_1, \dots, P_m$  merge into a single component  $P = \bigcup_{i \in [m]} P_i$ . the Duplicator updates
- 2164 his selection by removing all selected  $P_i$  and optionally adding  $P$ , while ensuring the total
- 2165 number of selected components is odd.
- 2166 3. *Swapping two pebbles p and p'*: the Spoiler swaps the positions of two pebbles, which does not
- 2167 affect the connected components, and therefore the Duplicator does nothing.

2168 the Spoiler wins the game if, at any point, there exists a path  $p$  such that both of its endpoints are

2169 covered by pebbles and the connected component containing  $\{p\}$  is selected by the Duplicator. If the

2170 Spoiler cannot achieve this throughout the game, the Duplicator wins. In the case of the  $k$ -spectral

2171 invariant GNN, there are  $k + 1$  pebbles, denoted  $p_{u_1}, \dots, p_{u_k}, p_v$ . Initially, all pebbles are placed

2172 outside the graph. the Spoiler first sequentially adds the pebbles  $p_{u_1}, \dots, p_{u_k}$  (using operation 1).

2173 The game proceeds in a cyclical manner. In each round, Spoiler selects an  $r \in [k]$  and freely chooses

2174 one of the following two actions:

- 2175 • For  $r = 1, 2, \dots, k$ , Spoiler removes pebble  $p_{u_r}$  (operation 2), and then re-adds it (operation 1).
- 2176 • For  $r = 1, 2, \dots, k$ , Spoiler adds pebble  $p_w$  (operation 1) adjacent to  $p_{u_r}$ , swaps  $p_{u_r}$  with  $p_w$
- 2177 (operation 3), and then removes  $p_w$  (operation 2).

2178 For a given graph  $F$ , let  $G(F)$  and  $H(F)$  denote the Fürer graph and the twisted Fürer graph with

2179 respect to  $F$ . Using similar reasoning as in the low-dimensional case, we can show that if the

2180 Spoiler cannot win the pebble game on  $F$ , then  $\chi_{G(F)}^{k\text{-Spec}}(G(F)) = \chi_{H(F)}^{k\text{-Spec}}(H(F))$ . Furthermore,

2181 analogous to the analysis of Lemma B.37, we can conclude that if the Spoiler wins the pebble game

2182 on  $F$ , then there exists a parallel tree decomposition  $T^r$  of  $F$  such that  $(F, T^r) \in \mathcal{S}^{k\text{-Spec}}$ . Thus, for

2183 any connected graph  $F \notin \mathcal{F}^{k\text{-Spec}}$ , there exist graphs  $G(F)$  and  $H(F)$  such that  $\text{hom}(F, G(F)) \neq$

2184  $\text{hom}(F, H(F))$  and  $\chi_G^{k\text{-Spec}}(G(F)) = \chi_H^{k\text{-Spec}}(H(F))$ . This completes the proof of the lemma.  $\square$

2185

2186

2187

2188 Finally, the proof of Theorem E.6 is completed by combining the results from Lemma E.7 and

2189 Lemma E.8.

2190

## 2191 F PROOF FOR SYMMETRIC POWER

2192

### 2193 F.1 PROPERTIES OF LOCAL $k$ -GNN

2194

2195 In this section, we review key properties of the local  $k$ -GNN as presented in previous works. We

2196 begin by formally introducing the update rule for the local  $k$ -GNN.

2197

2198 **Definition F.1.** Local  $k$ -GNN maintains a color  $\chi_G^{L(k)}(\mathbf{u})$  for each vertex  $k$ -tuple  $\mathbf{u} \in V_G^k$ . Initially,

2199  $\chi_G^{L(k), (0)}(\mathbf{u}) = \text{atp}_G(\mathbf{u})$ , called the isomorphism type of vertex  $k$ -tuple  $\mathbf{u}$ , where  $\text{atp}_G(\mathbf{u})$  is the

2200 *atomic type* of  $\mathbf{u}$ . Then, in each iteration  $t + 1$ ,

2201

$$2202 \chi_G^{L(k), (t+1)}(\mathbf{u}) = \text{hash} \left( \chi_G^{L(k), (t)}(\mathbf{u}), \left\{ \left\{ \chi_G^{L(k), (t)}(\mathbf{v}) : \mathbf{v} \in N_G^{(1)}(\mathbf{u}) \right\}, \dots, \left\{ \left\{ \chi_G^{L(k), (t)}(\mathbf{v}) : \mathbf{v} \in N_G^{(k)}(\mathbf{u}) \right\} \right\} \right), \right. \\ \left. 2203 \right) \quad (8)$$

2204

2205 where  $N_G^{(j)}(\mathbf{u}) = \{(u_1, \dots, u_{j-1}, w, u_{j+1}, \dots, u_k) : w \in N_G(u_j)\}$ . Denote the stable color as

2206  $\chi_G^{L(k)}(\mathbf{u})$ . The representation of graph  $G$  is defined as  $\chi_G^{L(k)}(G) := \{\{\chi_G^{L(k)}(\mathbf{u}) : \mathbf{u} \in V_G^k\}\}$ .

2207

2208 **Definition F.2 (Canonical Tree Decomposition).** Given a graph  $G = (V_G, E_G)$ , a canonical tree

2209

- 2209 1. The depth of  $T$  is even, i.e.,  $\max_{t \in V_T} \text{dep}_{T^r}(t)$  is even;
- 2210 2. Each tree node  $t \in V_T$  is associated to a multiset of vertices  $\beta_T(t) \subset V_G$ , called a *bag*. More-
- 2211 over,  $|\beta_T(t)| = k$  if  $\text{dep}_{T^r}(t)$  is *even* and  $|\beta_T(t)| = k + 1$  if  $\text{dep}_{T^r}(t)$  is *odd*;
- 2212 3. For all tree edges  $\{s, t\} \in E_T$  where  $\text{dep}_{T^r}(s)$  is even and  $\text{dep}_{T^r}(t)$  is odd,  $\beta_T(s) \subset \beta_T(t)$
- 2213 (where “ $\subset$ ” denotes the multiset inclusion relation);

- 2214 4. For each edge  $\{u, v\} \in V_G$ , there exists at least one tree node  $t \in V_T$  that contains the edge,  
 2215 i.e.,  $\{u, v\} \subset \beta_T(t)$ ;  
 2216  
 2217 5. For each vertex  $u \in V_G$ , all tree nodes  $t$  whose bag contains  $u$  form a (non-empty) collection.

2218 We further define set  $\mathcal{S}^{L(k)}$  as follows:

2219 **Definition F.3.**  $(F, T^r) \in \mathcal{S}^{L(k)}$  iff  $(F, T^r)$  satisfies F.2 with width  $k$ , and any tree node  $t$  of odd  
 2220 depth has only one child. Moreover, all vertex of  $F$  is contained in at least one node of  $t$ .  
 2221

2222 Then, we can obtain the following theorem of the homomorphic expressivity of Local  $k$ -GNN.

2223 **Theorem F.4.** Any graph  $G$  and  $H$  have the same representation under Local  $k$ -GNN (i.e.,  
 2224  $\chi_G^{L(k)}(G) = \chi_H^{L(k)}(H)$ ) iff  $\text{hom}(F, G) = \text{hom}(F, H)$  for all  $(F, T^r) \in \mathcal{S}^{L(k)}$ .  
 2225

## 2226 F.2 MAIN RESULT

2228 Since  $2k$ -local GNN is strictly weaker than  $2k$ -WL, we aim to extend previous result by showing  
 2229 that  $2k$ -local GNN can encode  $k$ -symmetric power of a graph. We state our main result as follows:

2230 **Theorem F.5.** The Local  $2k$ -GNN defined in Morris et al. (2020); Zhang et al. (2024a) can encode  
 2231 the symmetric  $k$ -th power. Specifically, for given graphs  $G$  and  $H$ , if  $G$  and  $H$  have the same  
 2232 representation under Local  $2k$ -GNN, then  $G^{\{k\}}$  and  $H^{\{k\}}$  have the same representation under the  
 2233 spectral invariant GNN defined in Section 2.1.  
 2234

## 2235 F.3 PROOF OF THEOREM F.5

2237 **Definition F.6.** Let  $\mu_1 < \mu_2 < \dots < \mu_m$  represent the distinct eigenvalues of the  $k$ -th order sym-  
 2238 metric power matrix of a graph  $G$ . Let  $E_i$  denote the eigenspace corresponding to  $\mu_i$ , and  $P_i^S$  the or-  
 2239 thogonal projection matrix from  $\mathbb{R}^{C_n^k}$  onto  $E_i$ . For  $u_1, u_2, \dots, u_{2k} \in V_G$ , if both  $\{\{u_1, u_2, \dots, u_k\}\}$   
 2240 and  $\{\{u_{k+1}, u_{k+2}, \dots, u_{2k}\}\}$  are multisets of  $k$  distinct vertices, then we define

$$2241 P_*^S(S_1, S_2) = (P_1^S(S_1, S_2), \dots, P_m^S(S_1, S_2)),$$

2242 where  $S_1 = \{\{u_1, u_2, \dots, u_k\}\}$  and  $S_2 = \{\{u_{k+1}, u_{k+2}, \dots, u_{2k}\}\}$ . Otherwise, we define

$$2243 P_*^S(\{\{u_1, u_2, \dots, u_k\}\}, \{\{u_{k+1}, u_{k+2}, \dots, u_{2k}\}\}) = \mathbf{0}.$$

2244 We encode the spectral information of the symmetric power into the aggregation of local  $2k$ -GNN,  
 2245 resulting in a variant of the local  $2k$ -GNN, defined as follows:

2248 **Definition F.7.** A local  $2k$ -GNN with symmetric power maintains a color  $\chi_G^{\text{SL}(2k)}(\mathbf{u})$  for each vertex  
 2249  $2k$ -tuple  $\mathbf{u} \in V_G^{2k}$ . Initially, the color is defined as

$$2250 \chi_G^{\text{SL}(2k), (0)}(\mathbf{u}) = (P_*^S(\{\{u_1, \dots, u_k\}\}, \{\{u_{k+1}, \dots, u_{2k}\}\}), \text{atp}_G(\mathbf{u})).$$

2252 Then, at each iteration  $t + 1$ , the update rule is given by:

$$2253 \chi_G^{\text{SL}(2k), (t+1)}(\mathbf{u}) = \text{hash} \left( \chi_G^{\text{SL}(2k), (t)}(\mathbf{u}), \{\{\chi_G^{\text{SL}(2k), (t)}(\mathbf{v}) : \mathbf{v} \in N_G^{(1)}(\mathbf{u})\}\}, \dots, \right. \\ 2254 \left. \{\{\chi_G^{\text{L}(2k), (t)}(\mathbf{v}) : \mathbf{v} \in N_G^{(k)}(\mathbf{u})\}\} \right), \quad (9)$$

2255 where  $N_G^{(j)}(\mathbf{u}) = \{(u_1, \dots, u_{j-1}, w, u_{j+1}, \dots, u_k) : w \in N_G(u_j)\}$ .

2259 The stable color is denoted as  $\chi_G^{\text{SL}(k)}(\mathbf{u})$ . The graph representation is then defined as

$$2260 \chi_G^{\text{SL}(k)}(G) := \{\{\chi_G^{\text{L}(k)}(\mathbf{u}) : \mathbf{u} \in V_G^{2k}\}\}.$$

2262 Next, we define the concept of a  $k$ -dimensional path as follows:

2263 **Definition F.8.** For a graph  $G$  and vertices  $u_1, \dots, u_k \in V_G$ , we define the neighboring multiset of  
 2264  $\{\{u_1, u_2, \dots, u_k\}\}$  as:

$$2265 N_G(\{\{u_1, u_2, \dots, u_k\}\}) = \bigcup_{r=1}^k \{\{u_1, \dots, u_{r-1}, v, u_{r+1}, \dots, u_k\} \mid v \in N_G(u_r)\}.$$

A  $k$ -dimensional path of length  $n$  is defined as a sequence  $(S_1, S_2, \dots, S_n)$ , where each  $S_1, \dots, S_n$  is a multiset of  $k$  elements, and for all  $r \in [n-1]$ ,  $S_r \in N_G(S_{r+1})$ . If the path further satisfies the condition that for all  $u \in S_r$  with  $r \in \{2, 3, \dots, n-1\}$  and  $v \in V_G$ ,  $u \in N_G(v)$  implies  $v \in S_i$  for some  $i \in \{r-1, r, r+1\}$ , then we denote  $(S_1, \dots, S_n)$  as a  $k$ -dimensional path of length  $n$ .

We then define set  $\mathcal{S}^{\text{SL}(k)}$  base on the definition of set  $\mathcal{S}^{\text{L}(k)}$ .

**Definition F.9.**  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$  iff  $(F, T^r)$  satisfies definition F.2 with width  $k$ , and any tree node  $t$  of odd depth has only one child. Furthermore, for tree node  $t \in V_T$  if  $\text{dep}_{T^r}(t)$  is even, we further associate it with a set of  $k$ -dimensional path  $\gamma_T(t)$ , called sub-bag. Specifically, for node  $t \in V_T$ , let  $\beta_T(t) = \{\{u_1, \dots, u_{2k}\}\}$ , then  $\gamma_T(t)$  contains  $k$ -dimensional path linking  $\{\{u_1, \dots, u_k\}\}$  and  $\{\{u_{k+1}, \dots, u_{2k}\}\}$ . Each vertex of  $F$  is contained in at least one node of  $T^r$ , either in bags or sub-bags.

**Lemma F.10.** Any graph  $G$  and  $H$  have the same representation under Local  $2k$ -GNN with symmetric power if  $\text{hom}(F, G) = \text{hom}(F, H)$  for all  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ .

*Proof.* To prove the theorem, we first define unfolding tree of local  $2k$ -GNN with symmetric power. Given a graph  $G$ ,  $2k$ -tuple  $\mathbf{u} \in V_G^{2k}$  and a non-negative integer  $D$ , the depth- $D$  unfolding tree of graph  $G$  at tuple  $\mathbf{u}$ , denoted as  $(F_G^{\text{SL}(D)}(\mathbf{u}), T_G^{\text{SL}(D)}(\mathbf{u}))$  is constructed as follows:

1. *Initialization.* We assume multiset  $\mathbf{u} = \{\{u_1, u_2, \dots, u_{2k}\}\}$ . At the beginning,  $F = G[\{\{u_1, u_2, \dots, u_{2k}\}\}]$ , and  $T$  only has a root node  $r$  with  $\beta_T(r) = \{\{u_1, u_2, \dots, u_{2k}\}\}$ . Define a mapping  $\pi : V_F \rightarrow V_G$  as  $\pi(u_i) = u_i, \forall i \in [2k]$ . For every  $k$ -dimensional walk  $\{\{u_1, \dots, u_k\}\} = S_1, \dots, S_n = \{\{u_{k+1}, \dots, u_{2k}\}\}$  with  $n \leq |V_G|^k$ , we introduce a  $k$ -dimensional path  $\{\{u_1, \dots, u_k\}\} = S'_1, S'_2, \dots, S'_n = \{\{u_{k+1}, \dots, u_{2k}\}\}$ , and we add  $(S'_1, S'_2, \dots, S'_n)$  to sub-bag  $\gamma_T(r)$ .
2. *Loop for  $D$  rounds.* For each leaf node  $t$  in  $T^r$ , do the following procedure for all  $i \in [2k]$ :  
Let  $\beta_T(t) = \{\{u_1, \dots, u_{2k}\}\}$ . For each  $w \in V_G$ , add a fresh child node  $t_w$  to  $T$  and designate  $t$  as its parent. Then, consider the following two cases:
  - (a) If  $w \notin \{\{\pi(u_1), \dots, \pi(u_{2k})\}\}$ , then add a fresh vertex  $z$  to  $F$  and extend  $\pi$  with  $\pi(z) = w$ . Define  $\beta_T(t_w) = \beta_T(t) \cup \{\{z\}\}$ . Then, add edges between  $z$  and  $\beta_T(t)$ , so that  $\pi$  is an isomorphism from  $F[\beta_T(t_w)]$  to  $G[\pi(\beta_T(t_w))]$ .
  - (b) If  $w \in \{\{\pi(u_1), \dots, \pi(u_{2k})\}\}$ , let  $w = \pi(u_r)$ . Then, we simply set  $\beta_T(t_w) = \beta_T(t) \cup \{\{u_r\}\}$  without modifying graph  $F$ .

Next, add a fresh child node  $t'_w$  in  $T^r$ , designate  $t_w$  as its parent, and set  $\beta_T(t'_w)$  and  $\gamma_T(t'_w)$  based on the following two cases:

- (a) If  $w \notin \{\{\pi(u_1), \dots, \pi(u_{2k})\}\}$ , then  $\beta_T(t'_w) = \{\{u_1, \dots, u_{i-1}, z, u_{i+1}, \dots, u_{2k}\}\}$ . For every  $k$ -dimensional walk  $S_1, \dots, S_n$  with  $n \leq |V_G|^k$ , we introduce  $k$ -dimensional path  $S_1 = S'_1, S'_2, \dots, S'_n = S_n$ . If  $i < k$ , then  $S_1 = \{\{u_1, \dots, u_{i-1}, z, \dots, u_k\}\}$ . If  $i = k$ , then  $S_1 = \{\{u_1, \dots, u_{i-1}, z\}\}$ , while if  $i > k$ , then  $S_1 = \{\{u_1, \dots, u_k\}\}$ . We denote  $S_2 = \{\{u_1, \dots, u_{i-1}, z, u_{i+1}, \dots, u_{2k}\}\} \setminus S_1$ . We add  $(S'_1, S'_2, \dots, S'_n)$  into sub-bag  $\gamma_T(t'_w)$ .
- (b) Conversely, if  $w \in \{\{\pi(u_1), \dots, \pi(u_{2k})\}\}$ , we assume that  $w = \pi(u_r)$ . Then  $\beta_T(t'_w) = \{\{u_1, \dots, u_{i-1}, u_r, u_{i+1}, \dots, u_{2k}\}\}$ . For every  $k$ -dimensional walk  $S_1, \dots, S_n$  with  $n \leq |V_G|^k$ , we introduce  $k$ -dimensional path  $S_1 = S'_1, S'_2, \dots, S'_n = S_n$ . If  $i < k$ , then  $S_1 = \{\{u_1, \dots, u_{i-1}, u_r, \dots, u_k\}\}$ . If  $i = k$ , then  $S_1 = \{\{u_1, \dots, u_{i-1}, u_r\}\}$ , while if  $i > k$ , then  $S_1 = \{\{u_1, \dots, u_k\}\}$ . We denote  $S_2 = \{\{u_1, \dots, u_{i-1}, u_r, u_{i+1}, \dots, u_{2k}\}\} \setminus S_1$ . We add  $(S'_1, S'_2, \dots, S'_n)$  into sub-bag  $\gamma_T(t'_w)$ .

We can see from the construction of unfolding tree that for all  $k$ -tuple  $\mathbf{u} \in V_G^{2k}$  and  $D > 0$ ,  $(F_G^{\text{SL}(D)}(\mathbf{u}), T_G^{\text{SL}(D)}(\mathbf{u})) \in \mathcal{S}^{\text{SL}(2k)}$ . Given  $(F, T^r), (\tilde{F}, \tilde{T}^r) \in \mathcal{S}^{\text{SL}(2k)}$ , we define a pair of mapping  $(\rho, \tau)$  as an isomorphism from  $(F, T^r)$  to  $(\tilde{F}, \tilde{T}^r)$ , denoted by  $(F, T) \cong (\tilde{F}, \tilde{T}^r)$ , if the following hold:

1.  $\rho$  is an isomorphism from  $F$  to  $\tilde{F}$ .
2.  $\tau$  is an isomorphism from  $T^r$  to  $\tilde{T}^r$  (ignoring  $\beta$  and  $\gamma$ ).
3. For any  $t \in V_{T^r}$ ,  $\rho(\beta_{T^r}(t)) = \beta_{\tilde{T}^r}(\tau(t))$ , and  $\rho(\gamma_{T^r}(t)) = \gamma_{\tilde{T}^r}(\tau(t))$ .

With similar analysis as Theorem B.8 we obtain that for any  $k$ -tuple  $\mathbf{u} \in V_G^k$  and  $\mathbf{v} \in V_H^k$ ,  $\chi_G^{\text{SL}(2k)(D)}(\mathbf{u}) = \chi_H^{\text{SL}(2k)(D)}(\mathbf{v})$  if there exists an isomorphism  $(\rho, \tau)$  from  $(F_G^{\text{SL}(D)}(\mathbf{u}), T_G^{\text{SL}(D)}(\mathbf{u}))$  to  $(F_H^{\text{SL}(D)}(\mathbf{v}), T_H^{\text{SL}(D)}(\mathbf{v}))$ . Given a graph  $G$  and  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ , we define

$$\text{treeCount}^{\text{SL}(2k)}((F, T^r), G) := \left| \left\{ \mathbf{u} \in V_G^{2k} : \exists D \in \mathbb{N}_+ \text{ s.t. } \left( F_G^{\text{SL}(D)}(\mathbf{u}), T_G^{\text{SL}(D)}(\mathbf{u}) \right) \cong (F, T^r) \right\} \right|.$$

Therefore, we can obtain that if  $\text{treeCount}^{\text{SL}(2k)}((F, T^r), G) = \text{treeCount}^{\text{SL}(2k)}((F, T^r), H)$  for all  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ , then  $\chi_G^{\text{SL}(2k)}(G) = \chi_H^{\text{SL}(2k)}(H)$ . Additionally, with similar analysis as Theorem B.20 and Theorem B.14, we can obtain that  $\text{treeCount}^{\text{SL}(2k)}((F, T^r), G) = \text{treeCount}^{\text{SL}(2k)}((F, T^r), H)$  for all  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$  if and only if  $\text{hom}((F, T^r), G) = \text{hom}((F, T^r), H)$  for all  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ . Therefore, we can obtain that if  $\text{hom}((F, T^r), G) = \text{hom}((F, T^r), H)$  for all  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ , then  $\chi_G^{\text{SL}(2k)}(G) = \chi_H^{\text{SL}(2k)}(H)$ . Thus, we finish the proof of the lemma.  $\square$

**Lemma F.11.** For all  $k \geq 1$ , we have  $\mathcal{S}^{\text{L}(2k)} = \mathcal{S}^{\text{SL}(2k)}$ .

*Proof.* We can directly see that  $\mathcal{S}^{\text{L}(2k)} \subset \mathcal{S}^{\text{SL}(2k)}$ , so it is sufficed to prove that for all  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ , there exists an alternative tree decomposition  $\tilde{T}^r$  such that  $(F, \tilde{T}^r) \in \mathcal{S}^{\text{L}(2k)}$ . We will prove that for  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ , if  $\max_{t \in V_{T^r}} |\gamma_{T^r}(t)| \geq 1$ , then we can construct  $\tilde{T}^r$  such that  $\max_{t \in V_{\tilde{T}^r}} |\gamma_{\tilde{T}^r}(t)| < \max_{t \in V_{T^r}} |\gamma_{T^r}(t)|$ . For  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ , let  $t = \arg \max_{t \in V_{T^r}} |\gamma_{T^r}(t)|$  and suppose  $(S_1, S_2, \dots, S_n) \in \gamma_{T^r}(t)$ . We apply the following modification to  $T^r$  to construct  $\tilde{T}^r$ :

1. We construct tree node  $t_1, t_2, \dots, t_{n-1}$  and  $\hat{t}_1, \hat{t}_2, \dots, \hat{t}_{n-1}$  such that  $\beta_{\tilde{T}^r}(t_r) = S_{r+1} \cup S_r \cup S_n$  and  $\beta_{\tilde{T}^r}(\hat{t}_r) = S_{r+1} \cup S_n$  for all  $r \in [n-1]$ .
2. We add  $\hat{t}_r$  as the child node of  $t_r$  for all  $r \in [n-1]$  and add  $t_r$  as the child node of  $\hat{t}_{r-1}$  for all  $r \in \{2, 3, \dots, n-1\}$ . Eventually, we add  $t_1$  as the child node of  $t$ .
3. We delete  $k$ -dimensional path from  $\gamma_{T^r}(t)$  and keep the bags of all  $t \in V_T$  and sub-bags of vertices in  $V_T \setminus \{t\}$  unchanged. Namely, we assume that  $\gamma_{\tilde{T}^r}(t) = \gamma_{T^r}(t) \setminus \{(S_1, \dots, S_n)\}$ . Moreover,  $\beta_{\tilde{T}^r}(t) = \beta_{T^r}(t)$  for all  $t \in V_T$  and  $\gamma_{\tilde{T}^r}(t) = \gamma_{T^r}(t)$  for all  $V_T \setminus \{t\}$ .

With the procedure above we can obtain  $(F, \tilde{T}^r) \in \mathcal{S}^{\text{SL}(2k)}$  such that  $\max_{t \in \tilde{T}^r} |\gamma_{\tilde{T}^r}(t)| < \max_{t \in T^r} |\gamma_{T^r}(t)|$ . If we recursively apply this procedure to modify  $\tilde{T}^r$ , we can eventually obtain  $\hat{T}^r$  such that  $\max_{t \in \hat{T}^r} |\gamma_{\hat{T}^r}(t)| = 0$ . Therefore,  $(F, \hat{T}^r) \in \mathcal{S}^{\text{L}(2k)}$ . Eventually, we have proven that for all  $(F, T^r) \in \mathcal{S}^{\text{SL}(2k)}$ , there exists an alternative decomposition  $\tilde{T}^r$  such that  $(F, \tilde{T}^r) \in \mathcal{S}^{\text{L}(2k)}$ . Thus, for all  $k \geq 1$ ,  $\mathcal{S}^{\text{L}(2k)} = \mathcal{S}^{\text{SL}(2k)}$ .  $\square$

Finally, we can finish the proof of Theorem F.5.

**Theorem F.12.** The Local  $2k$ -GNN defined in Morris et al. (2020); Zhang et al. (2024a) can encode the symmetric  $k$ -th power. Specifically, for given graphs  $G$  and  $H$ , if  $G$  and  $H$  have the same representation under Local  $2k$ -GNN, then  $G^{\{k\}}$  and  $H^{\{k\}}$  have the same representation under the spectral invariant GNN defined in Section 2.1.

*Proof.* According to Lemma F.11, the homomorphism expressivity of the vanilla Local  $2k$ -GNN is equivalent to that of the Local  $2k$ -GNN with symmetric power. Hence, the expressive power of the Local  $2k$ -GNN is the same as that of the Local  $2k$ -GNN with symmetric power. If there exist graphs  $G$  and  $H$  such that  $\chi_G^{\text{L}(k)}(G) = \chi_H^{\text{L}(k)}(H)$ , then it must follow that  $\chi_G^{\text{SL}(k)}(G) = \chi_H^{\text{SL}(k)}(H)$ . Therefore, we also have  $\chi_G^{\text{SL}(k), (0)}(G) = \chi_H^{\text{SL}(k), (0)}(H)$ , meaning that the symmetric  $k$ -th powers of  $G$  and  $H$  are cospectral. Moreover, it is straightforward that if graphs  $G$  and  $H$  have the same representation under a Local  $2k$ -GNN with symmetric power, then  $G^{\{k\}}$  and  $H^{\{k\}}$  also have the same representation under the spectral invariant GNN. Thus, the proof of the theorem is complete.  $\square$
