EKAN: EQUIVARIANT KOLMOGOROV-ARNOLD NETWORKS

Anonymous authors

Paper under double-blind review

ABSTRACT

Kolmogorov-Arnold Networks (KANs) have seen great success in scientific domains thanks to spline activation functions, becoming an alternative to Multi-Layer Perceptrons (MLPs). However, spline functions may not respect symmetry in tasks, which is crucial prior knowledge in machine learning. Previously, equivariant networks embed symmetry into their architectures, achieving better performance in specific applications. Among these, Equivariant Multi-Layer Perceptrons (EMLP) introduce arbitrary matrix group equivariance into MLPs, providing a general framework for constructing equivariant networks layer by layer. In this paper, we propose Equivariant Kolmogorov-Arnold Networks (EKAN), a method for incorporating matrix group equivariance into KANs, aiming to broaden their applicability to more fields. First, we construct gated spline basis functions, which form the EKAN layer together with equivariant linear weights. We then define a lift layer to align the input space of EKAN with the feature space of the dataset, thereby building the entire EKAN architecture. Compared with baseline models, EKAN achieves higher accuracy with smaller datasets or fewer parameters on symmetry-related tasks, such as particle scattering and the three-body problem, often reducing test MSE by several orders of magnitude. Even in nonsymbolic formula scenarios, such as top quark tagging with three jet constituents, EKAN achieves comparable results with EMLP using only 26% of the parameters, while KANs do not outperform MLPs as expected.

1 INTRODUCTION

Kolmogorov-Arnold Networks (KANs) (Liu et al., 2024b;a) are a novel type of neural network inspired by the Kolmogorov-Arnold representation theorem (Tikhomirov, 1991; Braun & Griebel, 2009), which offers an alternative to Multi-Layer Perceptrons (MLPs) (Haykin, 1998; Cybenko, 037 1989; Hornik et al., 1989). Unlike MLPs, which utilize fixed activation functions on nodes, KANs employ learnable activation functions on edges, replacing the linear weight parameters entirely with univariate functions parameterized as splines (De Boor & De Boor, 1978). On the other hand, each 040 layer of KANs can be viewed as spline basis functions followed by a linear layer (Dhiman, 2024). 041 This architecture allows KANs to achieve better accuracy in symbolic formula representation tasks 042 compared with MLPs, particularly in function fitting and scientific applications. Subsequent works 043 based on KANs have demonstrated superior performance in other areas, such as sequential data 044 (Vaca-Rubio et al., 2024; Genet & Inzirillo, 2024b;a; Xu et al., 2024), graph data (Bresson et al., 2024; De Carlo et al., 2024; Kiamari et al., 2024; Zhang & Zhang, 2024), image data (Cheon, 2024b;a; Azam & Akhtar, 2024; Li et al., 2024a; Seydi, 2024; Bodner et al., 2024), and so on. 046

However, KANs themselves perform poorly on non-symbolic formula representation tasks (Yu et al., 2024). One reason for this is that splines struggle to respect data type and symmetry, both of which play important roles in machine learning. Many recent works utilize symmetry in data to design network architectures, achieving better efficiency and generalization on specific tasks. For example, Convolutional Neural Networks (CNNs) (LeCun et al., 1989) and Group equivariant Convolutional Neural Networks (GCNNs) (Cohen & Welling, 2016a) leverage translational and rotational symmetries in image data, while DeepSets (Zaheer et al., 2017) and equivariant graph networks (Maron et al., 2018) exploit the permutation symmetry in set and graph data.

054 Equivariant Multi-Layer Perceptrons (EMLP) (Finzi et al., 2021) propose a general method that 055 allows MLPs to be equivariant with respect to arbitrary matrix groups for specific data types, thereby 056 unifying the aforementioned specialized network architectures. They construct the equivariance 057 constraint using discrete and infinitesimal generators of the matrix group, and then obtain equivariant 058 linear weights by solving this constraint. Next, they apply gated nonlinearities (Weiler et al., 2018a), which use the additional output of the previous layer as gate scalars. Due to the generality of matrix groups, EMLP outperforms non-equivariant baselines on several datasets with complex symmetries. 060

061 Inspired by EMLP, we propose Equivariant Kolmogorov-Arnold Networks (EKAN), which embed 062 matrix group equivariance into KANs. By specifying the data type and symmetry, EKAN can serve 063 as a general framework for applying KANs to various areas. In Section 2, we introduce the pre-064 liminary knowledge of group theory. In Section 3, we summarize related works. In Section 4, we construct a layer of EKAN. We add gate scalars to the input and output space of each layer, and de-065 fine gated spline basis functions between the input and post-activation space. To ensure equivariance 066 when linearly combining gated basis functions, we construct the equivariant constraint and solve for 067 the equivariant linear weights similar to EMLP. In Section 5, we build the entire EKAN architecture. 068 We insert a lift layer before the first layer and discard the gate scalars from the output of the final 069 layer, so that the input and output space of EKAN can be consistent with the original dataset. In Section 6, we evaluate EKAN on tasks with known symmetries. We show that EKAN can achieve 071 higher accuracy than baseline models with smaller datasets or fewer parameters. In Section 7, we 072 conclude this work. In Figure 1, we compare the architectures of MLPs, EMLP, KANs, and EKAN. 073

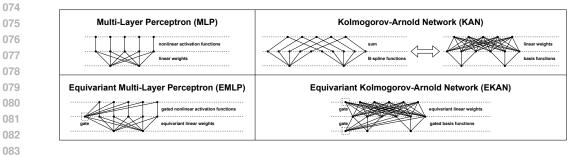

Figure 1: Comparison of the architectures of Multi-Layer Perceptrons (MLPs), Equivariant Multi-Layer Perceptrons (EMLP), Kolmogorov-Arnold Networks (KANs), and Equivariant Kolmogorov-Arnold Networks (EKAN).

In summary, our contributions are as follows:

- We propose EKAN, an architecture that makes KANs equivariant to matrix groups. To our knowledge, EKAN is the first attempt to combine equivariance with KANs, and we expect that it can serve as a general framework to broaden the applicability of KANs to more areas.
- We specify the space structures of the EKAN Layer and define gated spline basis functions. We theoretically prove that gated basis functions can ensure equivariance between the gated input space and the post-activation space. Then, we insert a lift layer to preprocess the raw input feature, which aligns the input space of EKAN with the feature space of the dataset.
- Experiments on tasks with matrix group equivariance, such as particle scattering and the three-body problem, demonstrate that EKAN often significantly outperforms baseline models, even with smaller datasets or fewer parameters. In the task of non-symbolic formula representation, where KANs are not proficient, such as top quark tagging with three jet constituents, EKAN can still achieve comparable results with EMLP while using only 26%of the parameters.

Before presenting related works and our method, we first introduce some preliminary knowledge of 107 group theory.

Groups and generators. The matrix group \tilde{G} is a subgroup of the general linear group GL(n), which consists of $n \times n$ invertible matrices. Each group element $g \in G$ can be decomposed into a continuous and a finite component $g = g_1 g_2$. We can obtain the continuous component g_1 from a Lie algebra element $A \in \mathfrak{g}$ through the exponential map $\exp : \mathfrak{g} \to G$, i.e., $g_1 = \exp(A) =$ $\sum_{k=0}^{\infty} \frac{A^k}{k!}$. Representing the space where the Lie algebra resides as a basis $\{A_i\}_{i=1}^{D}$, we have $g_1 =$ $\exp\left(\sum_{i=1}^{D} \alpha_i A_i\right)$. On the other hand, the finite component g_2 can be generated by a set of group elements $\{h_i\}_{i=1}^M$ and their inverses $h_{-k} = h_k^{-1}$, formally speaking $g_2 = \prod_{i=1}^N h_{k_i}$. Overall, we can express the matrix group element as:

$$g = \exp\left(\sum_{i=1}^{D} \alpha_i A_i\right) \prod_{i=1}^{N} h_{k_i},\tag{1}$$

where $\{A_i\}_{i=1}^D$ are called infinitesimal generators and $\{h_i\}_{i=1}^M$ are called discrete generators. We introduce common matrix groups and their generators in Appendix A.

Group representations. The group representation $\rho_V : \widetilde{G} \to \operatorname{GL}(m)$ maps group elements to $m \times m$ invertible matrices, which describes how group elements act on the vector space $V = \mathbb{R}^m$ through linear transformations. For $g_1, g_2 \in \hat{G}$ it satisfies $\rho_V(g_1g_2) = \rho_V(g_1)\rho_V(g_2)$. Similarly, the Lie algebra representation is defined as $d\rho_V : \mathfrak{g} \to \mathfrak{gl}(m)$, and for $A_1, A_2 \in \mathfrak{g}$, we have $d\rho_V(A_1+A_2) = d\rho_V(A_1) + d\rho_V(A_2)$. We can relate the Lie group representation to the Lie algebra representation through the exponential map. Specifically, for $A \in \mathfrak{g}$, $\rho_V(\exp(A)) = \exp(d\rho_V(A))$ holds. Then, combining with Equation (1), the matrix group representation can be written as:

$$\rho_V(g) = \exp\left(\sum_{i=1}^D \alpha_i \mathrm{d}\rho_V(A_i)\right) \prod_{i=1}^N \rho_V(h_{k_i}).$$
(2)

We can construct the complex vector space from the base vector space using the dual (*), direct sum (\oplus) , and tensor product (\otimes) operations. To give a concrete example, let V_1 and V_2 be base vector spaces. The multi-channel vector space, matrix space and parameter space of the linear mapping $V_1 \rightarrow V_2$ can be represented as $V_1 \oplus V_2$, $V_1 \otimes V_2$, and $V_2 \otimes V_1^*$, respectively. In general, given a matrix group G, we can normalize the vector space U into a polynomial-like form with respect to the base vector space V (the space where the group representation is the identity mapping $\rho_V(q) = q$; intuitively, the transformation matrix is the matrix group element itself):

$$U = \bigoplus_{a=1}^{A} T(p_a, q_a) = \bigoplus_{a=1}^{A} V^{p_a} \otimes (V^*)^{q_a},$$
(3)

where $V^{p_a} = \underbrace{V \otimes V \otimes \cdots \otimes V}_{p_a}$ and $(V^*)^{q_a} = \underbrace{V^* \otimes V^* \otimes \cdots \otimes V^*}_{q_a}$. Its group representation and Lie algebra representation can be generated by the following rules:

$$\begin{cases} \rho_{V^*}(g) = \rho_V(g^{-1})^\top, \\ \rho_{V_1 \oplus V_2}(g) = \rho_{V_1}(g) \oplus \rho_{V_2}(g), \\ \rho_{V_1 \otimes V_2}(g) = \rho_{V_1}(g) \otimes \rho_{V_2}(g), \end{cases} \begin{cases} d\rho_{V^*}(A) = -d\rho_V(A)^\top, \\ d\rho_{V_1 \oplus V_2}(A) = d\rho_{V_1}(A) \oplus d\rho_{V_2}(A), \\ d\rho_{V_1 \otimes V_2}(A) = d\rho_{V_1}(A) \boxplus d\rho_{V_2}(A), \end{cases}$$
(4)

where \oplus is the direct sum, \otimes is the Kronecker product, and \boxplus is the Kronecker sum.

Equivariance and invariance. The symmetry can be divided into equivariance and invariance, meaning that when a transformation is applied to the input space, the output space either transforms in the same way or remains unchanged. Formally, given a group G, a function $f: U_i \to U_o$ is equivariant if:

$$\forall g \in G, v_i \in U_i: \quad \rho_o(g)f(v_i) = f(\rho_i(g)v_i), \tag{5}$$

where ρ_i and ρ_o are group representations of U_i and U_o , respectively. Specifically, when $\rho_o(g) = I$, the function f is invariant.

Equivariant networks. Equivariant networks have gained significant attention in recent years due to their ability to respect and leverage symmetries in data. GCNNs (Cohen & Welling, 2016a) embed 166 discrete group equivariance into traditional CNNs through group convolutions. Steerable CNNs 167 (Cohen & Welling, 2016b) introduce steerable filters, which provide a more flexible and efficient 168 way to achieve equivariance compared with GCNNs. Subsequently, SFCNNs (Weiler et al., 2018b) 169 and E(2)-equivariant steerable CNNs (Weiler & Cesa, 2019) extend GCNNs and steerable CNNs to 170 continuous group equivariance, while 3D Steerable CNNs (Weiler et al., 2018a) extend these models to 3D volumetric data. On the other hand, some works use partial differential operators (PDOs) to 171 construct equivariant networks (Shen et al., 2020; 2021; 2022; He et al., 2022; Li et al., 2024b). 172 Based on these theoretical frameworks, equivariant networks are widely applied in various fields, 173 such as mathematics (Zhao et al., 2022), physics (Wang et al., 2020), biochemistry (Bekkers et al., 174 2018; Winkels & Cohen, 2019; Graham et al., 2020), and others. 175

176 Equivariant Multi-Layer Perceptrons (EMLP). EMLP (Finzi et al., 2021) embeds matrix group 177 equivariance into MLPs layerwise. Given the input space U_i and output space U_o , the linear weight 178 matrix $W \in U_o \otimes U_i^*$ should satisfy Equation (5), i.e., $\forall g \in G, v_i \in U_i : \rho_o(g)Wv_i = W\rho_i(g)v_i$. 179 So the coefficients of each term in v_i are equal $\forall g \in \tilde{G} : \rho_o(g)W = W\rho_i(g)$. Flattening the linear 180 weight matrix W into a vector, we have $\forall g \in \widetilde{G} : \lceil \rho_o \otimes \rho_i(g^{-1})^\top \rceil \operatorname{vec}(W) = \operatorname{vec}(W)$. Combined 181 with Equation (4), the linear weight matrix W is invariant in the space $U_o \otimes U_i^*$: 182

$$\forall g \in \widetilde{G}: \quad \rho_{o,i}(g) \operatorname{vec}(W) = \operatorname{vec}(W), \tag{6}$$

185 where $\rho_{o,i} = \rho_o \otimes \rho_i^*$ is the group representation of $U_o \otimes U_i^*$. Decomposing the group representation 186 $\rho_{\alpha,i}(q)$ into discrete and infinitesimal generators as shown in Equation (2), Equation (6) is equivalent to the following constraint:

$$C \operatorname{vec}(W) = \begin{bmatrix} d\rho_{o,i}(A_1) \\ \vdots \\ d\rho_{o,i}(A_D) \\ \rho_{o,i}(h_1) - I \\ \vdots \\ \rho_{o,i}(h_M) - I \end{bmatrix} \operatorname{vec}(W) = 0.$$

$$(7)$$

By performing singular value decomposition (SVD) on the coefficient matrix C, we can obtain its 196 nullspace, which corresponds to the subspace where the equivariant linear weights reside.

199 Kolmogorov-Arnold Networks (KANs). KANs (Liu et al., 2024b;a) place learnable activation functions on the edges and then sum them to obtain the output nodes, replacing the fixed activation 200 functions applied to the output nodes of linear layers in MLPs. Formally, the *l*-th KAN layer can be 201 expressed as: 202

$$x_{l+1,j} = \sum_{i=1}^{n_l} \phi_{l,j,i}(x_{l,i}), \quad j = 1, \dots, n_{l+1},$$
(8)

where n_l is the number of nodes in the *l*-th layer, $x_{l,i}$ is the value of the *i*-th node in the *l*-th layer, 206 and $\phi_{l,j,i}$ is the activation function that connects $x_{l,i}$ to $x_{l+1,j}$. In practice, $\phi_{l,j,i}$ consists of a 207 spline function and a silu function. The spline basis functions are determined by grids, which are 208 updated based on the input samples. Then we can write the post-activation of $\phi_{l,i,i}$ as $\phi_{l,i,i}(x_{l,i}) =$ 209 $\sum_{b=0}^{G+k-1} w_{l,j,i,b} B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k, \text{ and } B_{l,i,b} \text{ represent the number of } W_{l,j,i,b} B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k, \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,i,G+k} \text{silu}(x_{l,i}), \text{ where } G, k \text{ and } B_{l,i,b}(x_{l,i}) + w_{l,i,G+k} \text{silu}(x_{l,i}), \text{ and } B_{l,i,$ 210 grid intervals, the order, and the b-th basis function of splines at node $x_{l,j}$, respectively. Therefore, 211 the KAN layer can be viewed as spline basis functions $B_{l,i,b}$ and a silu function, followed by a linear 212 layer with $w_{l,i,i,b}$ as parameters (Dhiman, 2024): 213

214
215
$$x_{l+1,j} = \sum_{i=1}^{n_l} \left[\sum_{b=0}^{G+k-1} w_{l,j,i,b} B_{l,i,b}(x_{l,i}) + w_{l,j,i,G+k} \operatorname{silu}(x_{l,i}) \right], \quad j = 1, \dots, n_{l+1}.$$
(9)

EKAN LAYER

 In this section, we construct the EKAN layer, which is equivariant with respect to the matrix group G. First, we define the space structures and explain their relationships. Then, we introduce gated basis functions and equivariant linear weights, which together form a layer of EKAN. Finally, we present the implementation details of grid updates. We summarize the space structures and network architecture of the EKAN layer in Figure 2.

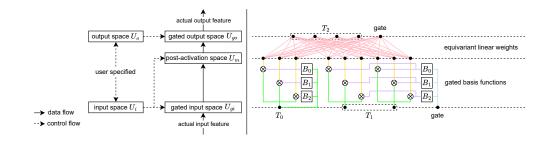

Figure 2: (Left) The space structures of the EKAN layer and their relationships. (Right) The architecture of the EKAN layer, which consists of gated basis functions and equivariant linear weights.

4.1 SPACE STRUCTURES

A key aspect of equivariant networks is how group elements act on the feature space. Therefore, unlike conventional networks, which only focus on the dimensions of the feature space, equivariant networks need to further clarify the structure of the feature space. For example, for the group SO(2), two feature spaces $U_1 = V \oplus V = \mathbb{R}^2 \oplus \mathbb{R}^2$ and $U_2 = V \otimes V = \mathbb{R}^2 \otimes \mathbb{R}^2$ have different group representations ρ_{U_1} and ρ_{U_2} , but conventional networks treat them as the same space $U = \mathbb{R}^4$.

We specify the input space and the output space of EKAN layer as U_i and U_o , respectively. Their structures can be normalized into the form of Equation (3). In particular, for ease of later discussion, we extract the scalar space terms $T_0 = T(0,0)$ and rewrite them as:

$$\begin{cases} U_{i} = c_{i}T_{0} \oplus \left[\bigoplus_{a=1}^{A_{i}} T(p_{i,a}, q_{i,a})\right], \\ U_{o} = c_{o}T_{0} \oplus \left[\bigoplus_{a=1}^{A_{o}} T(p_{o,a}, q_{o,a})\right], \end{cases}$$
(10)
where $p_{i,a}^{2} + q_{i,a}^{2} > 0, p_{o,a}^{2} + q_{o,a}^{2} > 0$, and $cT_{0} = \underbrace{T_{0} \oplus T_{0} \oplus \cdots \oplus T_{0}}_{0}.$

We have to emphasize that the actual input/output feature does not lie within U_i/U_o . To align with gated basis functions, we add a gate scalar T_0 to each non-scalar term $T(p_{i,a}, q_{i,a})/T(p_{o,a}, q_{o,a})$ in U_i/U_o to obtain the actual input/output space. We denote this actual input/output space as the gated input/output space U_{qi}/U_{qo} :

 $\begin{cases} U_{gi} = c_i T_0 \oplus \left[\bigoplus_{a=1}^{A_i} T(p_{i,a}, q_{i,a}) \right] \oplus A_i T_0, \\ U_{go} = c_o T_0 \oplus \left[\bigoplus_{a=1}^{A_o} T(p_{o,a}, q_{o,a}) \right] \oplus A_o T_0. \end{cases}$ (11)

As shown in Equation (9), we split the KAN layer into basis functions and linear weights. From this perspective, we correspondingly construct gated basis functions and equivariant linear weights to form the EKAN layer. We refer to the space where the activation values reside after gated basis functions and before equivariant linear weights as the post-activation space U_m . The structure of U_m depends on U_i , which we will elaborate on in Section 4.2.

We summarize the aforementioned space structures and their relationships in Figure 2 (Left). The user first specifies the input space U_i and the output space U_o for the EKAN layer. Then the gated input space U_{gi} and the post-activation space U_m are calculated based on U_i , and the gated output space U_{qo} is calculated based on U_o . The actual input feature in U_{qi} passes through gated basis functions to obtain the activation value in U_m , which then passes through equivariant linear weights to obtain the actual output feature in U_{ao} .

4.2 GATED BASIS FUNCTIONS271

Gating mechanisms are widely used in various areas, not only in language models to improve performance (Dauphin et al., 2017; Shazeer, 2020; Gu & Dao, 2023) but also in the design of equivariant networks (Weiler et al., 2018a; Finzi et al., 2021). Inspired by this, we propose gated basis functions to make the basis functions in KANs (spline basis functions and the silu function) equivariant. Suppose that the input feature $v_{gi} \in U_{gi}$ can be decomposed according to the space structure shown in Equation (11):

286 287 288

289 290 291

295

296

297 298

299

304

306

311 312 313

316

322

 $v_{gi} = \left(\bigoplus_{a=1}^{c_i} s_{i,a}\right) \oplus \left(\bigoplus_{a=1}^{A_i} v_{i,a}\right) \oplus \left(\bigoplus_{a=1}^{A_i} s'_{i,a}\right),\tag{12}$

where $s_{i,a}, s'_{i,a} \in T_0$ and $v_{i,a} \in T(p_{i,a}, q_{i,a})$. For the non-scalar term $v_{i,a}$, we apply the basis functions to the corresponding gate scalar $s'_{i,a}$ and then multiply the result by $v_{i,a}$. For the scalar term $s_{i,a}$, we consider it as its own gate scalar, which is equivalent to applying basis functions element-wise to $s_{i,a}$. Formally, the post-activation value $v_m \in U_m$ can be written as:

$$v_m = \bigoplus_{b=0}^{G+k} v_{m,b},\tag{13}$$

where

$$v_{m,b} = \begin{cases} \left[\bigoplus_{a=1}^{c_i} s_{i,a} B_b(s_{i,a}) \right] \oplus \left[\bigoplus_{a=1}^{A_i} v_{i,a} B_b(s'_{i,a}) \right], & b < G+k, \\ \left[\bigoplus_{a=1}^{c_i} s_{i,a} \operatorname{silu}(s_{i,a}) \right] \oplus \left[\bigoplus_{a=1}^{A_i} v_{i,a} \operatorname{silu}(s'_{i,a}) \right], & b = G+k. \end{cases}$$
(14)

Note that $v_{m,b} \in c_i T_0 \oplus \left[\bigoplus_{a=1}^{A_i} T(p_{i,a}, q_{i,a}) \right] = U_i$. Therefore, we obtain the structure of the post-activation space U_m :

$$U_m = (G + k + 1)U_i.$$
 (15)

The following theorem guarantees the equivariance between the gated input space and the postactivation space (see Appendix B for proof).

Theorem 1. Given a matrix group \hat{G} , the gated input space U_{gi} and the post-activation space U_m can be expressed in the forms of Equations (11) and (15), respectively. The function $f: U_{gi} \to U_m$ is defined by Equations (12), (13) and (14), that is, $v_m = f(v_{gi})$. Then, f is equivariant:

$$\forall g \in \widetilde{G}, v_{gi} \in U_{gi}: \quad \rho_m(g)f(v_{gi}) = f(\rho_{gi}(g)v_{gi}), \tag{16}$$

where ρ_{qi} and ρ_m are group representations of U_{qi} and U_m , respectively.

4.3 EQUIVARIANT LINEAR WEIGHTS

The output feature $v_{go} \in U_{go}$ is obtained by a linear combination of the post-activation value $v_m \in U_m$. Let $U_i = \mathbb{R}^{d_i}$ and $U_{go} = \mathbb{R}^{d_{go}}$, then Equation (15) indicates that $U_m = \mathbb{R}^{(G+k+1)d_i}$. The linear weight matrix $W \in \mathbb{R}^{d_{go} \times (G+k+1)d_i}$ can be partitioned as $W = [W_0 W_1 \dots W_{G+k}]$, where $W_b \in \mathbb{R}^{d_{go} \times d_i}$. Combining with Equation (13), we have:

$$v_{go} = W v_m = \sum_{b=0}^{G+k} W_b v_{m,b}.$$
 (17)

To ensure the equivariance between the post-activation space and the gated output space, we obtain:

$$\forall g \in \widetilde{G}, v_m \in U_m: \quad \rho_{go}(g)Wv_m = W\rho_m(g)v_m, \tag{18}$$

where ρ_{go} is the group representation of U_{go} . Using the structure of U_m shown in Equation (15) and applying the rules from Equation (4), we can derive that $\rho_m(g) = \bigoplus_{b=0}^{G+k} \rho_i(g)$, where ρ_i is the group representation of U_i . Therefore, from Equation (13), we have $\rho_m(g)v_m = \bigoplus_{b=0}^{G+k} \rho_i(g)v_{m,b}$. Then Equation (18) can be written as:

$$\forall g \in \widetilde{G}, \{v_{m,b}\}_{b=0}^{G+k} \in U_i: \quad \sum_{b=0}^{G+k} \rho_{go}(g) W_b v_{m,b} = \sum_{b=0}^{G+k} W_b \rho_i(g) v_{m,b}. \tag{19}$$

The coefficients of each term in $\{v_{m,b}\}_{b=0}^{G+k}$ are equal:

$$\forall g \in \widetilde{G}, b \in \{0, 1, \dots, G+k\}: \quad \rho_{go}(g)W_b = W_b\rho_i(g). \tag{20}$$

Flattening the linear weight blocks $\{W_b\}_{b=0}^{G+k}$ into vectors, we obtain:

$$\forall g \in \widetilde{G}, b \in \{0, 1, \dots, G+k\}: \quad \rho_{go,i}(g) \operatorname{vec}(W_b) = \operatorname{vec}(W_b), \tag{21}$$

where $\rho_{go,i} = \rho_{go} \otimes \rho_i^*$ is the group representation of $U_{go} \otimes U_i^*$. We use the same method as EMLP (Finzi et al., 2021) to solve for the equivariant basis Q and equivariant projector $P = QQ^{\top}$ of vec (W_b) . Similar to the transition from Equation (6) to Equation (7), we decompose the group representation $\rho_{go,i}(g)$ into discrete and infinitesimal generators to obtain the following constraint:

$$\forall b \in \{0, 1, \dots, G+k\}: \quad C \operatorname{vec}(W_b) = \begin{bmatrix} d\rho_{go,i}(A_1) \\ \vdots \\ d\rho_{go,i}(A_D) \\ \rho_{go,i}(h_1) - I \\ \vdots \\ \rho_{go,i}(h_M) - I \end{bmatrix} \operatorname{vec}(W_b) = 0. \tag{22}$$

Note that the equivariant linear weight blocks $\{W_b\}_{b=0}^{G+k}$ lie in the same subspace, which corresponds to the nullspace of the coefficient matrix C. We can obtain it via SVD.

We summarize the architecture of the EKAN layer in Figure 2 (Right). In this example, the 345 EKAN layer is equivariant with respect to a 2-dimensional matrix group \hat{G} (such as the SO(2)) 346 347 group). The user specifies the input space $U_i = T_0 \oplus T_1$ (where we abbreviate $T(p,0) = V^p$ as T_p), which represents a scalar space and a vector space, and specifies the output space $U_o = T_2$, 348 which represents a matrix space. Then, the gated input space $U_{gi} = T_0 \oplus T_1 \oplus T_0$ and the gated 349 output space $U_{qo} = T_2 \oplus T_0$ each add a gate scalar to the vector space T_1 and the matrix space T_2 . 350 The basis functions are applied to the gate scalars of T_0 (itself) and T_1 , which are then multiplied 351 by the original terms to obtain the post-activation space $U_m = 3U_i$. The linear weights $W \in \mathbb{R}^{5 \times 9}$ 352 between U_m and U_{qo} are within the subspace determined by Equation (22) to ensure equivariance. 353

4.4 GRID UPDATE

356 Similar to KANs (Liu et al., 2024b), EKAN updates grids based on the input activations. At the 357 same time, the linear weights should also be updated in order to keep the output features un-358 changed. Let the post-activation values of the grids before and after the update be denoted as 359 $V_m, V'_m \in \mathbb{R}^{N \times (G+k+1)d_i}$, where N is the number of samples. We first project the linear weight 360 blocks into the equivariant subspace as $vec(\widetilde{W}_b) = Pvec(W_b)$ and compute the output activations $V_{go} = V_m \widetilde{W}^\top = \sum_{b=0}^{G+k} V_{m,b} \widetilde{W}_b^\top$, where P is the equivariant projector obtained from Equa-361 362 tion (22). Then, the updated equivariant linear weights \widetilde{W}' should satisfy $V_{go} = V'_m \widetilde{W}'^{\top}$, and we 363 have $W' = V_{qo}^{\top}(V_m'^{\top})^{\dagger}$. We finally restore the updated linear weight blocks $\operatorname{vec}(W_b') = P^{\dagger}\operatorname{vec}(W_b')$. 364

5 EKAN ARCHITECTURE

In this section, we construct the entire EKAN architecture. The main body of EKAN is composed of stacked EKAN layers. The output space of the *l*-th layer serves as the input space of the (l+1)-th layer, which we refer to as the latent space U_l . For the dataset, we usually know its data type, or in other words, how group elements act on it. To embed this prior knowledge into EKAN, we set the input space of the first layer as the feature space of the dataset U_i and the output space of the final layer as the label space of the dataset U_o .

However, the actual input/output features of the EKAN layer stack lie in U_{gi}/U_{go} . Therefore, we need to add extensions to align the network with the dataset. First, the gate scalars of the actual output feature are directly dropped to obtain the final output label of EKAN, which resides in U_o . Then, we add a lift layer before the first layer to preprocess the raw input feature of EKAN, which is essentially an equivariant linear layer between U_i and U_{qi} (see Section 4.3 for more details).

391 392

Figure 3: (Left) The space structures of EKAN and their relationships. (Right) The EKAN architecture, which consists of a lift layer and stacked EKAN layers.

393 We summarize the space structures and network architecture of EKAN in Figure 3. The space struc-394 tures of EKAN can be analogous to the dimensions of a conventional network. The user specifies the latent space U_l of EKAN, which corresponds to specifying the hidden dimension in a conventional 396 network. The input space U_i and the output space U_o are determined by the dataset, similar to how 397 the input and output dimensions are defined in a conventional network. In the concrete example, the feature space and label space of the dataset are $U_i = T_0 \oplus T_1$ and $U_o = T_2$, respectively. After passing through the lift layer, a new gate scalar is added to the raw input feature for T_1 , resulting in 399 the actual input feature $U_{gi} = T_0 \oplus T_1 \oplus T_0$ for the first EKAN layer. The gate scalar in the actual 400 output space $U_{go} = T_2 \oplus T_0$ of the last EKAN layer is dropped to obtain the final output label. 401

6 EXPERIMENTS

In this section, we evaluate the performance of EKAN on regression and classification tasks with known symmetries. Compared with MLPs, KANs, and EMLP, EKAN achieves lower test loss and higher test accuracy with smaller datasets or fewer parameters.

409 6.1 PARTICLE SCATTERING

In electron-muon scattering, we can observe the four-momenta of the incoming electron, incoming muon, outgoing electron, and outgoing muon, denoted as $q^{\mu}, p^{\mu}, \tilde{q}^{\mu}, \tilde{p}^{\mu} \in \mathbb{R}^4$, respectively. We aim to predict the matrix element, which is proportional to the cross-section (Finzi et al., 2021):

$$\mathcal{M}|^2 \propto [p^{\mu} \tilde{p}^{\nu} - (p^{\alpha} \tilde{p}_{\alpha} - p^{\alpha} p_{\alpha}) g^{\mu\nu}] [q_{\mu} \tilde{q}_{\nu} - (q^{\alpha} \tilde{q}_{\alpha} - q^{\alpha} q_{\alpha}) g_{\mu\nu}].$$
(23)

According to Einstein's summation convention, in a monomial, if an index appears once as a superscript and once as a subscript, it indicates summation over that index. The metric tensor is given by $g_{\mu\nu} = g^{\mu\nu} = \text{diag}(1, -1, -1, -1)$, and $a_{\mu} = g_{\mu\nu}a^{\nu} = (a^0, -a^1, -a^2, -a^3)$. The matrix element is invariant under Lorentz transformations. In other words, this task exhibits O(1,3) invariance (see Appendix A.2 for more details), with the feature space $U_i = 4T_1$ and the label space $U_o = T_0$.

420 We embed the group O(1,3) and its subgroups $SO^+(1,3)$ and SO(1,3) equivariance into EKAN. 421 Models are evaluated on synthetic datasets with different training set sizes, which are generated by sampling $q^{\mu}, p^{\mu}, \tilde{q}^{\mu}, \tilde{p}^{\mu} \sim \mathcal{N}(0, \frac{1}{4^2})$. Both EKAN and KAN have the depth of L = 2, the 422 spline order of k = 3, and grid intervals of G = 3. Although the lift layer increases the parameter 423 overhead, we set the width of the middle layer in EKAN to $n_1 = 1000$ (shape as [16, 1000, 1], 424 and the software will automatically calculate the appropriate feature space structure based on the 425 user-specified dimension), and set the width of the middle layer in KAN to $n_1 = 3840$ (shape as 426 [16, 3840, 1]) to keep the parameter count similar. Both EMLP and MLP have the depth of L = 4427 and the middle layer width of $n_1 = n_2 = n_3 = 384$ (shape as [16, 384, 384, 384, 1]). In these 428 settings, EKAN (435k) has fewer parameters than EMLP (450k) and KAN (461k). We provide 429 more implementation details in Appendix C.1. 430

431 We repeat experiments with three different random seeds and report the mean \pm std of the test MSE in Table 1. The results of EMLP and MLP come from the original paper (Finzi et al., 2021) under

Table 1: Test MSE of different models on the particle scattering dataset with different training set sizes. We present the results in the format of mean \pm std.

the same settings. Although EMLP performs better than non-equivariant models, our EKAN with different group equivariance further surpasses it comprehensively, especially showing an orders-of-magnitude advantage on large datasets (training set size $\geq 10^3$). Moreover, our EKAN with just 10^3 training samples achieves approximately 10% of the test MSE of EMLP with 10^4 training samples.

6.2 THREE-BODY PROBLEM

The study of the three-body problem on a plane (Greydanus et al., 2019) focuses on the motion of three particles, with their center of mass at the origin, under the influence of gravity. Their trajecto-ries are chaotic and cannot be described by an analytical solution. Specifically, we observe the motion states of three particles over the past four time steps, denoted as $\{q_{i1}, p_{i1}, q_{i2}, p_{i2}, q_{i3}, p_{i3}\}_{i=t-4}^{t-1}$ and predict their motion states at time t, denoted as $\{q_{t1}, p_{t1}, q_{t2}, p_{t2}, q_{t3}, p_{t3}\}$. Here, $q_{ij} \in \mathbb{R}^2$ and $p_{ij} \in \mathbb{R}^2$ indicate the position and momentum coordinates of the j-th particle at time i, respectively. The dataset contains 30k training samples and 30k test samples. When the input motion states are simultaneously rotated by a certain angle or reflected along a specific axis, the output motion states should undergo the same transformation. Therefore, this task has O(2) equivariance (see Appendix A.1 for more details), with the feature space $U_i = 4 \times 6T_1 = 24T_1$ and the label space $U_o = 6T_1$.

We embed the group O(2) and its subgroup SO(2) equivariance into EKAN and EMLP. Both EKAN and KAN have the depth of L = 2, the spline order of k = 3, and grid intervals of G = 3, while both EMLP and MLP have the depth of L = 4. The number of parameters is controlled by adjusting the middle layer width N for comparison (the shape of EKAN and KAN is [48, N, 12], while the shape of EMLP and MLP is [48, N, N, N, 12]). More implementation details can be found in Appendix C.2.

Table 2: Test MSE of different models with different numbers of parameters on the three-body problem dataset. We present the results in the format of mean \pm std.

Models	10 ^{4.5}	$10^{4.75}$	Number of parameters 10^5	$10^{5.25}$	$10^{5.5}$
MLP	$ (4.84 \pm 0.19) \times 10^{-3}$	$(4.70\pm 0.30)\times 10^{-3}$	$(4.60\pm 0.12)\times 10^{-3}$	$(4.17\pm 0.24)\times 10^{-3}$	$(4.24\pm 0.27)\times 10^{-3}$
EMLP-SO(2) EMLP-O(2)	$ \begin{array}{ c c c c c c c c c c c c c c c c c c c$	$\begin{array}{c} (6.87 \pm 5.29) \times 10^{-3} \\ (1.18 \pm 0.22) \times 10^{-3} \end{array}$	$\begin{array}{c} (3.55\pm1.59)\times10^{-3} \\ (1.42\pm1.86)\times10^{-2} \end{array}$	$\begin{array}{c} (2.01 \pm 1.09) \times 10^{-3} \\ (7.37 \pm 7.60) \times 10^{-3} \end{array}$	$\begin{array}{c} (5.34 \pm 3.78) \times 10^{-3} \\ (1.37 \pm 0.07) \times 10^{-3} \end{array}$
KAN	$(4.32 \pm 3.08) \times 10^{-1}$	$(2.21\pm 0.65)\times 10^{-2}$	$(1.18\pm 0.18)\times 10^{-2}$	$(1.23\pm 0.34)\times 10^{-2}$	$(9.15 \pm 1.76) \times 10^{-3}$
EKAN-SO(2) (Ours) EKAN-O(2) (Ours)	$ \begin{vmatrix} (1.12 \pm 0.13) \times \mathbf{10^{-3}} \\ (1.48 \pm 0.37) \times 10^{-3} \end{vmatrix} $	$\begin{array}{c} ({\bf 7.06 \pm 0.65}) \times {\bf 10^{-4}} \\ ({\bf 1.12 \pm 0.24}) \times {\bf 10^{-3}} \end{array}$	$\begin{array}{c} ({\bf 6.09 \pm 0.27}) \times {\bf 10^{-4}} \\ (7.91 \pm 0.52) \times 10^{-4} \end{array}$	$\begin{array}{c} (4.26\pm0.19)\times\mathbf{10^{-4}}\\ (6.06\pm0.36)\times10^{-4} \end{array}$	$\begin{array}{c} (4.84\pm0.68)\times\mathbf{10^{-4}}\\ (6.02\pm0.88)\times10^{-4} \end{array}$

The mean \pm std of the test MSE over three runs with different random seeds are reported in Table 2. Our EKAN-SO(2) and EKAN-O(2) consistently outperform baseline models with the same number of parameters, often by orders of magnitude. Notably, our EKAN with $10^{4.5}$ parameters achieves comparable or even lower test MSE than baseline models with $10^{5.5}$ parameters, saving 90% of the parameter overhead.

486 6.3 TOP QUARK TAGGING

527

The research on top quark tagging (Kasieczka et al., 2019) involves classifying hadronic tops from the QCD background. In particle collision experiments, top quark decays or other events produce several jet constituents. We observe the four-momenta $p_1^{\mu}, p_2^{\mu}, p_3^{\mu} \in \mathbb{R}^4$ of the three jet constituents with the highest transverse momentum p_T , and predict the event label (1 for top, 0 for QCD). The category of the event will not change when all jet constituents undergo the same Lorentz transformation. Consequently, this task possesses O(1,3) invariance (see Appendix A.2 for more details), with the feature space $U_i = 3T_1$ and the label space $U_o = T_0$.

Similar to particle scattering, we embed the group O(1,3) and its subgroups $SO^+(1,3)$ and SO(1,3)495 equivariance into EKAN and EMLP. We sample training sets of different sizes from the original 496 dataset for evaluation. Both EKAN and KAN have the depth of L = 2, the spline order of k = 3, 497 and grid intervals of G = 3. We set the width of the middle layer in EKAN to $n_1 = 200$ (shape as 498 [12, 200, 1]) and the width of the middle layer in KAN to $n_1 = 384$ (shape as [12, 384, 1]) to control 499 the number of parameters. Both EMLP and MLP have the depth of L = 4 and the middle layer 500 width $n_1 = n_2 = n_3 = 200$ (shape as [12, 200, 200, 200, 1]). We apply the sigmoid function to 501 the model's output and use BCE as the loss function for binary classification. More implementation 502 details are provided in Appendix C.3.

Table 3: Test accuracy (%) of different models on the top quark tagging dataset with different training set sizes. We present the results in the format of mean \pm std.

Models	10^{2}	$10^{2.5}$	$\begin{array}{c} {\rm Training \ set \ size} \\ 10^3 \end{array}$	$10^{3.5}$	10^{4}	Parameters

KAN	49.89 ± 0.39	49.91 ± 0.43	49.89 ± 0.37	50.00 ± 0.02	49.84 ± 0.25	35K
EKAN-SO ⁺ $(1,3)$ (Ours) EKAN-SO $(1,3)$ (Ours) EKAN-O $(1,3)$ (Ours)	$\begin{array}{ } \textbf{71.92} \pm \textbf{0.88} \\ \textbf{70.49} \pm \textbf{2.85} \\ \textbf{71.68} \pm \textbf{1.21} \end{array}$	$\begin{array}{c} {\bf 73.98 \pm 0.39} \\ {\bf 73.96 \pm 0.37} \\ {\bf 73.95 \pm 0.36} \end{array}$	$\begin{array}{c} 76.15 \pm 0.11 \\ 76.15 \pm 0.11 \\ 76.15 \pm 0.11 \end{array}$	$\begin{array}{c} 76.69 \pm 0.08 \\ 76.69 \pm 0.08 \\ 76.69 \pm 0.07 \end{array}$	$\begin{array}{c} 76.93 \pm 0.02 \\ 76.93 \pm 0.02 \\ 76.93 \pm 0.03 \end{array}$	34 K

We report the mean \pm std of the test accuracy over three runs with different random seeds, as well as the number of parameters of the models in Table 3. Since we have not observed all the jet constituents, the relationship between the labels and input features cannot be accurately expressed as an explicit function. In this case of non-symbolic formula representation, KAN cannot achieve higher accuracy with fewer parameters than MLP as expected. On the other hand, our EKAN achieves comparable results with EMLP using approximately 26% of the parameters, improving test accuracy by $0.23\% \sim 6.44\%$ on small datasets (training set size $< 10^4$), while decreasing by 0.19% on large datasets (training set size $= 10^4$).

7 CONCLUSION

528 To our knowledge, this work is the first attempt to combine equivariance and KANs. We view 529 the KAN layer as a combination of spline functions and linear weights, and accordingly define the 530 (gated) input space, post-activation space, and (gated) output space of the EKAN layer. Gated ba-531 sis functions ensure the equivariance between the gated input space and the post-activation space, 532 while equivariant linear weights guarantee the equivariance between the post-activation space and 533 the gated output space. The prior work has demonstrated that "EMLP > MLP" on tasks with sym-534 metries and "KAN > MLP" on symbolic formula representation tasks. Our experimental results 535 further indicate that on symbolic formula representation tasks with symmetries, "EKAN > EMLP" and "EKAN > KAN". Moreover, on non-symbolic formula representation tasks with symmetries, 536 although it may be that "KAN < MLP", we show that "EKAN > EMLP". We expect that EKAN can 537 become a general framework for applying KANs to more fields, such as computer vision and natural 538 language processing, just as EMLP unifies classic works like CNNs and DeepSets.

A COMMON MATRIX GROUPS AND THEIR GENERATORS

704 A.1 GROUPS SO(2) and O(2)

The group SO(2) represents rotation transformations in two-dimensional space. Its group elements can be expressed as:

$$R(\theta) = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}.$$
 (24)

710 It corresponds to an infinite generator:

$$A_1 = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}.$$
 (25)

Then we can obtain the group elements through the exponential map $R(\theta) = \exp(\theta A_1)$.

The group O(2) represents orthogonal transformations in two-dimensional space, including rotations and reflections. Based on the group SO(2), it has an additional discrete generator:

$$h_1 = \begin{bmatrix} 1 & 0\\ 0 & -1 \end{bmatrix}.$$
 (26)

A.2 GROUPS $SO^+(1,3)$, SO(1,3), and O(1,3)

The group $SO^+(1,3)$ represents Lorentz transformations that preserve both orientation and the direction of time. It includes six infinitesimal generators:

$$\begin{cases}
A_{1} = \begin{bmatrix}
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}, A_{2} = \begin{bmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}, A_{3} = \begin{bmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0
\end{bmatrix}, A_{4} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & -1 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}, A_{5} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 \\
0 & -1 & 0 & 0
\end{bmatrix}, A_{6} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0
\end{bmatrix},$$
(27)

where A_1, A_2, A_3 correspond to Lorentz boosts, and A_4, A_5, A_6 correspond to spatial rotations.

The group SO(1, 3) represents Lorentz transformations that preserve orientation. Based on the group SO⁺(1, 3), it has an additional discrete generator:

$$h_1 = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix},$$
(28)

741 which corresponds to orientation reversal.

The group O(1,3) represents all Lorentz transformations. Based on the group SO(1,3), it has an additional discrete generator:

$$h_2 = \begin{bmatrix} -1 & 0 & 0 & 0\\ 0 & 1 & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{bmatrix},$$
(29)

which corresponds to time reversal.

B PROOF OF THEOREM 1

Theorem 1. Given a matrix group \widetilde{G} , the gated input space U_{gi} and the post-activation space U_m can be expressed in the forms of Equations (11) and (15), respectively. The function $f: U_{gi} \to U_m$ is defined by Equations (12), (13) and (14), that is, $v_m = f(v_{gi})$. Then, f is equivariant:

$$\forall g \in \widetilde{G}, v_{gi} \in U_{gi}: \quad \rho_m(g)f(v_{gi}) = f(\rho_{gi}(g)v_{gi}), \tag{16}$$

where ρ_{qi} and ρ_m are group representations of U_{qi} and U_m , respectively.

Proof. Let $v_{m,b} = f_b(v_{qi})$, then Equation (13) can be written as:

 $f(v_{gi}) = \bigoplus_{b=0}^{G+k} f_b(v_{gi}).$ Using the structure of U_m shown in Equation (15) and applying the rules from Equation (4), we can derive the group representation of U_m :

$$\rho_m(g) = \bigoplus_{k=0}^{G+k} \rho_i(g), \tag{31}$$

(30)

where ρ_i is the group representation of U_i .

Combining Equations (30) and (31), we have:

$$\rho_m(g)f(v_{gi}) = \bigoplus_{b=0}^{G+k} \rho_i(g)f_b(v_{gi}).$$
(32)

Note that the group transformation in the scalar space T_0 is the identity transformation, then we can obtain the group representation of U_{gi} from Equation (11):

$$\rho_{gi}(g) = I_{c_i} \oplus \left[\bigoplus_{a=1}^{A_i} \rho_{i,a}(g) \right] \oplus I_{A_i},$$
(33)

where $\rho_{i,a}$ is the group representation of $T(p_{i,a}, q_{i,a})$.

Therefore, applying the group transformation to v_{qi} in Equation (12) results in:

$$\rho_{gi}(g)v_{gi} = \left(\bigoplus_{a=1}^{c_i} s_{i,a}\right) \oplus \left(\bigoplus_{a=1}^{A_i} \rho_{i,a}(g)v_{i,a}\right) \oplus \left(\bigoplus_{a=1}^{A_i} s'_{i,a}\right).$$
(34)

Substitute Equation (34) into Equation (14):

$$f_b(\rho_{gi}(g)v_{gi}) = \begin{cases} \left[\bigoplus_{a=1}^{c_i} s_{i,a}B_b(s_{i,a})\right] \oplus \left[\bigoplus_{a=1}^{A_i} \rho_{i,a}(g)v_{i,a}B_b(s'_{i,a})\right], & b < G+k, \\ \left[\bigoplus_{a=1}^{c_i} s_{i,a}\mathrm{silu}(s_{i,a})\right] \oplus \left[\bigoplus_{a=1}^{A_i} \rho_{i,a}(g)v_{i,a}\mathrm{silu}(s'_{i,a})\right], & b = G+k. \end{cases}$$
(35)

Similar to Equation (33), we can derive the group representation of U_i from Equation (10):

$$\rho_i(g) = I_{c_i} \oplus \left[\bigoplus_{a=1}^{A_i} \rho_{i,a}(g) \right].$$
(36)

Note that the right-hand side of Equation (35) is the result of applying $\rho_i(g)$ to $f_b(v_{qi})$, which means:

$$f_b(\rho_{gi}(g)v_{gi}) = \rho_i(g)f_b(v_{gi}).$$
 (37)

Substitute Equation (37) into Equation (30):

$$f(\rho_{gi}(g)v_{gi}) = \bigoplus_{b=0}^{G+k} \rho_i(g)f_b(v_{gi}).$$
(38)

Combining Equations (32) and (38), Equation (16) is proven.

С IMPLEMENTATION DETAILS

C.1 PARTICLE SCATTERING

In particle scattering, we generate training sets of different sizes, and the corresponding test sets have the same sizes as the training sets. We train EKAN using the Adan optimizer (Xie et al., 2024) with the learning rate of 3×10^{-3} and the batch size of 500. For datasets with the training set size < 1000, we set the number of epochs to 7000, while for datasets with the training set size ≥ 1000 , we set the number of epochs to 15000, which is sufficient for the MSE loss to converge to the minimum. We perform this experiment on a single-core NVIDIA GeForce RTX 3090 GPU with available memory of 24576 MiB.

810 C.2 THREE-BODY PROBLEM

In the three-body problem, we control the number of parameters by adjusting the middle layer width N of the model. We list the correspondence between the model's shape and the number of parameters in Table 4. We train all models using the Adan optimizer (Xie et al., 2024) with the learning rate of 3×10^{-3} , the batch size of 500, and for 5000 epochs. The grids of EKAN and KAN are updated every 5 epochs and stop updating at the 50th epoch. We perform this experiment on a single-core NVIDIA GeForce RTX 3090 GPU with available memory of 24576 MiB.

Table 4: The correspondence between the model's shape and the number of parameters.

	Number of parameters						
Models	$10^{4.5}$	$10^{4.75}$	10 ⁵	$10^{5.25}$	$10^{5.5}$		
MLP	[48, 111, 111, 111, 12]	[48, 153, 153, 153, 12]	[48, 209, 209, 209, 12]	[48, 283, 283, 283, 12]	[48, 383, 383, 383,		
EMLP	[48, 84, 84, 84, 12]	[48, 110, 110, 110, 12]	[48, 147, 147, 147, 12]	[48, 214, 214, 214, 12]	48, 281, 281, 281, 281,		
KAN	[48, 76, 12]	[48, 134, 12]	[48, 238, 12]	[48, 423, 12]	[48, 752, 12]		
EKAN (Ours)	[48, 45, 12]	[48, 88, 12]	[48, 151, 12]	[48, 262, 12]	[48, 457, 12]		

C.3 TOP QUARK TAGGING

In top quark tagging, we train all models using the Adan optimizer (Xie et al., 2024) with the learning rate of 3×10^{-3} and the batch size of 500. For datasets with the training set size ≤ 1000 , we set the number of epochs to 1000, while for datasets with the training set size > 1000, we set the number of epochs to 2000, which is sufficient for the BCE loss to converge to the minimum. The grids of EKAN and KAN are updated every 5 epochs and stop updating at the 50th epoch. We perform this experiment on a single-core NVIDIA GeForce RTX 3090 GPU with available memory of 24576 MiB.
