# Taxonomy-Guided Zero-Shot Recommendations with LLMs

Anonymous ACL submission

#### Abstract

 With the emergence of large language models (LLMs) and their ability to perform a variety of tasks, their application in recommender sys- tems (RecSys) has shown promise. However, we are facing significant challenges when de- ploying LLMs into RecSys, such as limited prompt length, unstructured item information, and un-constrained generation of recommen- dations, leading to sub-optimal performance. To address these issues, we propose a novel method using a taxonomy dictionary. This method provides a systematic framework for categorizing and organizing items, improving the clarity and structure of item information. By incorporating the taxonomy dictionary into 016 LLM prompts, we achieve efficient token uti- lization and controlled feature generation, lead- ing to more accurate and contextually relevant recommendations. Our Taxonomy-guided Rec- ommendation (TAXREC) approach features a two-step process: one-time taxonomy catego- rization and LLM-based recommendation, en- abling zero-shot recommendations without the need for domain-specific fine-tuning. Exper- imental results demonstrate TAXREC signifi-026 cantly enhances recommendation quality com- pared to traditional zero-shot approaches, show- casing its efficacy as personal recommender with LLMs. Code is available at [https://](https://anonymous.4open.science/r/TaxRec) [anonymous.4open.science/r/TaxRec](https://anonymous.4open.science/r/TaxRec).

#### **031** 1 Introduction

 Due to the emergent ability [\(Wei et al.,](#page-9-0) [2022\)](#page-9-0), large language models (LLMs) have triggered the purse of artificial general intelligence [\(Fei et al.,](#page-8-0) [2022\)](#page-8-0), where an artificial intelligence (AI) system can solve numerous tasks. Tasks that were previ- ously completed separately are now combined into one language modeling task by using prompt tem- plates to turn them into sentences. As shown in Fig- ure [1\(](#page-1-0)a), one single LLM [\(Achiam et al.,](#page-8-1) [2023\)](#page-8-1) can act as our personal assistant to complete a series of

tasks such as question answering [\(Tan et al.,](#page-9-1) [2023\)](#page-9-1), **042** machine translation [\(Zhang et al.,](#page-9-2) [2023\)](#page-9-2) and gram- **043** mar checking [\(Yasunaga et al.,](#page-9-3) [2021\)](#page-9-3). Besides, **044** LLM-based assistant can also provide reasonable **045** recommendations with its own knowledge within **046** the pre-trained parameters [\(Gao et al.,](#page-8-2) [2023\)](#page-8-2). With- **047** out the need for fine-tuning on historical user-item **048** interactions, it acts as the zero-shot recommenders, **049** which greatly extends LLMs toward a more gener-  $050$ alized all-task-in-one AI assistant. **051**

Acting as the assistant for recommendation, **052** LLMs face several challenges when it meets the **053** requirement from recommender system (RecSys) **054** as shown in Figure [1\(](#page-1-0)b). (1) Limited prompt length **055** prohibits input of all items. In RecSys, the size **056** of item pool effortlessly grows over millions with **057** each represented by tens of tokens, which easily **058** surpasses the prompt length limit [\(Pal et al.,](#page-9-4) [2023\)](#page-9-4) 059 of LLMs. Let alone the long context also causes de- **060** coding problems [\(Liu et al.,](#page-8-3) [2024\)](#page-8-3) even the whole **061** item pool is small enough to fit within the prompt. **062** (2) Vague and unstructured item title and descrip- **063** tion. The text information of items is provided at **064** the will of merchant, which is usually unstructured **065** and vague [\(Ni et al.,](#page-8-4) [2019\)](#page-8-4) to understand without **066** sufficient contexts. As shown in Figure [1\(](#page-1-0)b), the 067 title "1984" can represent the year/book/movie and **068** "Emma" is able to represent people name/book. Di- **069** rect recommendation with the raw item titles can **070** suffer from the ambiguity prompt issue and leads **071** to inferior performance. (3) Un-constrained gener- **072** ation out of candidate item pools. The generation **073** process of LLMs is un-constrained, and can easily **074** be un-matchable within the item pool, especially **075** for the unstructured titles. For example, the LLMs **076** can generate an item "Punch-Out!!!" that totally **077** out of the item pool when we only provide user's **078** historical interactions. With the direct text-based **079** generation, it is also compute intensive and mostly **080** infeasible to calculate the ranking score for all can- **081** didate items within the pool.  $082$ 

<span id="page-1-0"></span>

Figure 1: (a) LLMs are zero-shot recommenders without knowing other user-item interactions when acting as personal recommendation assistant. (b) Three challenges occur when integrating RecSys within the all-task-in-one LLM assistant, i.e., limited prompt length, vague item title and unconstrained generation.

 In this paper, we propose using taxonomy dic- tionary to cope with previously mentioned chal- lenges. Taxonomy is able to provide a systematic framework for identifying, organizing, and group- ing items. For each dataset, we first retrieve the taxonomy dictionary from LLM to obtain the cate- gorization knowledge of the domain and categorize all candidate items into structured item pool. It al- leviates the vague item title/description problem by providing more item context information. For ex- ample, the item "1984" is more clarified as "Type: Book, Genre: Fiction, Theme: Power, ...". When prompting LLM for recommendation, we add the taxonomy dictionary within the prompt to inform LLM the candidate items information.

 The taxonomy dictionary is a condensed cate- gorization of whole item pool. Compared with adding all candidate items, adding the dictionary can greatly save the tokens needed to inform LLM the candidates information, alleviating the limited prompt length challenge. Instead of directly gen- erating tokens within the item title, we propose to generate categorized features from the taxonomy dictionary. As the taxonomy dictionary can be eas- ily feed within the prompt, it is more controllable to generate features within the dictionary with our designed prompt template. We finally calculate the feature matching score within the categorized item pool to rank the items for recommendation.

 Our taxonomy-based approach is a two step pro- cess. The first is a one-time taxonomy categoriza- tion step, which retrieves knowledge from LLM to build taxonomy and categorized item pool. The second is LLM-based Recommendation step to in- ference user's preference based on the historical in-teractions. This approach effectively handles large

item pools, making it feasible to work within LLM **119** token limits, leading to a more efficient, accurate, **120** and scalable recommendation process. Our contri- **121** butions are summarized as: **122**

- The development of a systematic taxonomy **123** dictionary framework to categorize and orga- **124** nize items, enhancing the structure and clarity **125** of item information. **126**
- We propose TAXREC, a taxonomy-based **127** method to retrieve knowledge and enhance **128** LLM's ability as personal recommender. **129**
- Experiments show significant improvement **130** of TAXRECover current zero-shot recom- **131** menders, proving the effectiveness of our pro- **132** posed item taxonomy categorization. **133**

#### 2.1 LLM for Recommendations **135**

Recommendation systems play a critical role in **136** assisting users in finding relevant and personalized **137** items or content. With the emergence of LLMs **138** in recent years, there has been a growing inter- **139** est in harnessing the power of these models to **140** enhance recommendation systems. LLM-based **141** recommender systems can be mainly categorized **142** [i](#page-9-5)nto two types: discriminative and generative [\(Wu](#page-9-5) **143** [et al.,](#page-9-5) [2023\)](#page-9-5). The core idea of discriminative LLM- **144** based recommender systems is to utilize discrimi- **145** native LLMs to learn better representations of users **146** and items from contextual information for down- **147** [s](#page-9-6)tream tasks [\(Hou et al.,](#page-8-5) [2022;](#page-8-5) [Li et al.,](#page-8-6) [2023;](#page-8-6) [Xiao](#page-9-6) **148** [et al.,](#page-9-6) [2022;](#page-9-6) [Zhang et al.,](#page-9-7) [2022;](#page-9-7) [Yuan et al.,](#page-9-8) [2023;](#page-9-8) **149** [Yao et al.,](#page-9-9) [2022\)](#page-9-9). Unlike discriminative methods, 150 generative LLM-based recommendation systems **151**

<span id="page-2-0"></span>

Figure 2: The proposed TAXREC for zero-shot LLM-based recommendation. (a) One-time Taxonomy Categorization step aims to generate in-domain taxonomy and enrich/categorize item's title into structured text information. (b) LLM-based Recommendation step provide ranked item lists for users based on the user's historical interactions.

 leverage the generative ability of LLMs to make recommendations. They achieve this by translat- ing the traditional ranking-based recommendation tasks into natural language tasks. Compared with score computing and ranking strategies, they apply techniques such as prompt tuning and in-context learning to make LLMs able to generate the rec- ommendations directly. [\(Geng et al.,](#page-8-7) [2022\)](#page-8-7) is one of the first text-to-text generative recommendation methods, which used the pre-trained T5 as the back- bone. Recently, many methods explored the possi- bility of using LLMs to generate recommendations without fine-tuning [\(Dai et al.,](#page-8-8) [2023;](#page-8-8) [Gao et al.,](#page-8-2) [2023;](#page-8-2) [Liu et al.,](#page-8-9) [2023;](#page-8-9) [Lyu et al.,](#page-8-10) [2023;](#page-8-10) [Wang et al.,](#page-9-10) [2023c\)](#page-9-10). [\(Wang et al.,](#page-9-11) [2023b\)](#page-9-11) integrated database to LLMs to serve as autonomous agents for multiple recommendation tasks. [\(Wang et al.,](#page-9-12) [2023a\)](#page-9-12) used LLMs to augment the user-item interaction graph for recommendation. [\(Lyu et al.,](#page-8-10) [2023\)](#page-8-10) conducted a comprehensive investigation on how different types of prompts will influence the recommendation re- sults. While [\(Wang et al.,](#page-9-10) [2023c\)](#page-9-10) proposed a multi- round self-reflection framework for LLM-based sequential recommendation. However, previous works did not consider the problem that text rep- resentations of items are vague and unstructured, which will hinder LLM's recommendation abil- ity. In this paper, we propose a taxonomy-guided framework to solve this problem.

#### **181** 2.2 Zero-shot Recommendations

 Zero-shot recommendation has emerged as a sig- nificant area in the field of recommendation sys- tems. Unlike traditional systems that rely on model training, zero-shot recommendation systems aim to

predict user preferences without parameter adjust- **186** ment. Various methodologies have been explored **187** to address this challenge. For instance, a content- **188** [b](#page-8-11)ased approach leverages item attributes [\(Lian](#page-8-11) **189** [et al.,](#page-8-11) [2018\)](#page-8-11). Other methods utilize pre-trained lan- **190** guage models and embeddings to capture item and **191** [u](#page-8-12)ser characteristics from textual information [\(Ding](#page-8-12) **192** [et al.,](#page-8-12) [2022;](#page-8-12) [Hou et al.,](#page-8-5) [2022;](#page-8-5) [Li et al.,](#page-8-6) [2023\)](#page-8-6). With **193** the rise of LLMs in recent years, several studies **194** have explored their potential for making zero-shot **195** recommendations [\(Hou et al.,](#page-8-13) [2024;](#page-8-13) [Wang and Lim,](#page-9-13) **196** [2023;](#page-9-13) [He et al.,](#page-8-14) [2023;](#page-8-14) [Feng et al.,](#page-8-15) [2024;](#page-8-15) [Wang et al.,](#page-9-11) **197** [2023b\)](#page-9-11). However, these studies faced the issue of **198** limited context length in LLMs, which prevents the **199** input of all items. Some approaches addressed this **200** by using external tools or information [\(Wang et al.,](#page-9-11) **201** [2023b;](#page-9-11) [Feng et al.,](#page-8-15) [2024\)](#page-8-15), while others employed **202** a plug-in recommendation model to pre-select a **203** [s](#page-9-13)mall candidate pool [\(Hou et al.,](#page-8-13) [2024;](#page-8-13) [Wang and](#page-9-13) 204 [Lim,](#page-9-13) [2023;](#page-9-13) [He et al.,](#page-8-14) [2023\)](#page-8-14). None of these meth- **205** ods have been able to solve this problem solely **206** using the knowledge from LLMs. This paper pro- **207** poses a taxonomy-guided LLM recommender that **208** compresses the entire item pool using an LLM- **209** generated taxonomy, enabling zero-shot recommen- **210** dations without relying on external knowledge. **211**

# 3 Methodology **<sup>212</sup>**

In this paper, we aim to use LLMs as zero-shot rec- **213** ommenders. To achieve this, we propose a frame- **214** work TAXREC that uses taxonomy as an intermedi- **215** ate to retrieve the knowledge in LLMs. Specifically, **216** our TAXREC contains two phases. The first one **217** is a one-time taxonomy categorization phase, and **218**

# **225** zero-shot recommenders when users directly seek

 k recommended items is from the candidate item **pool**  $\mathcal{I} = \{i_j\}_{j=1}^{|\mathcal{I}|}$  only based on user's historical 229 interactions  $\mathcal{H} = \{i_1, i_2, ..., i_{|\mathcal{H}|}\}\$ and the knowl-edge within LLMs. As a pure text-based approach,

**232** The task can be then represented as designing a

- **233** LLM-based function as:
- **234 i**<sub>1</sub>, **i**<sub>2</sub>, ..., **i**<sub>k</sub> =  $f_{LLM}(\mathcal{H})$ . (1)
- **231** each item i is a title string as shown in Figure [2.](#page-2-0)

**235** In TAXREC, we further propose a taxonomy

236 dictionary  $\mathcal T$  as an intermediate to better retrieve **237** knowledge from LLMs, as well as a categorized

<span id="page-3-2"></span>**240** 3.2 One-time Taxonomy Categorization

239 **interactions**  $\mathcal{H}^{\mathcal{C}} = \{i_1^C, i_2^C, ..., i_{\mathcal{H}^{\mathcal{C}}}^C\}.$ 

238 item pool  $\mathcal{I}^{\mathcal{C}} = \{i_j^C\}_{j=1}^{\mathcal{I}^{\mathcal{C}}}$  and categorized historical

**219** the second one is the LLM-based recommendation

**226** recommendations. The task is to generate the Tok-

 The first step is a one-time generation, which aims to structure and clarify items into a categorized item pool. The original item text representation is vague and unstructured, which poses challenges for LLMs to understand and infer user's inter- est. As the first item within the pool shown in Figure [2\(](#page-2-0)a), "1984" can be represented as either year/book/movie. Without sufficient in-domain background knowledge, direct recommendation in zero-shot manner with these vague and unstruc-tured textual information is challenging for LLMs.

 To make LLMs better understand the key infor- mation in the historical interactions, we first extract the in-domain taxonomy dictionary from LLMs with a designed taxonomy generation prompt:

$$
\mathcal{T} = f_{LLM}(P_{\text{Taxonomy\_Gen}}),\tag{2}
$$

257 where  $P_{\text{Taxonomy Gen}}$  is the Taxonomy Generation Prompt as shown in Table [1.](#page-3-0) It is designed to re- trieve the in-domain knowledge from LLM to better classify items. As shown in Figure [2,](#page-2-0) we can obtain the important attributes to classify books such as Genre, Theme, Language, etc. With a well-defined 263 taxonomy dictionary  $T$ , we are able to enrich and categorize each item i as:

<span id="page-3-1"></span>
$$
i^C = f_{LLM}(P_{\text{Categorization}}|i, \mathcal{T}), \tag{3}
$$

where  $P_{\text{Categorization}}$  is the Categorization Prompt as 266 shown in Table [1](#page-3-0) to obtain *i*'s categorized feature 267 list as  $i^C = [f_1, f_2, ..., f_{|i^C|}]$ . We can structure and **268** enrich item textual descriptions with knowledge 269 from LLMs. For example, as shown in the cate- **270** gorized item pool in Figure [2\(](#page-2-0)a), the book "1984" **271** is enriched with "fiction" as genre and "power" as **272** theme. Compared with the origional vague book **273** title, the enriched texts provide more detailed in- **274** formation to assist LLMs inference user's interests. **275** The categorized item pool  $\mathcal{I}^C$  is obtained by cate-<br>276 gorizing items in  $\mathcal I$  with Equation [3.](#page-3-1)  $277$ 

Though we infer LLMs two times in this step, **278** this is a one-time operation for the current domain, **279** and the results could be stored for next step usage. **280**

# 3.3 LLM-based Recommendation **281**

In the second step, we take the advantage of  $\mathcal{I}^C$ and  $\mathcal T$  generated in Section [3.2,](#page-3-2) and build an LLM-  $283$ based recommender for the user. The process is **284** shown in Figure [2\(](#page-2-0)b). We first process each user's **285** historical interactions H to categorized historical 286 interactions  $\mathcal{H}^C$  by mapping item from  $\mathcal{I}^C$ . In this 287 way, the item representation will be structured and **288** enriched based on the taxonomy. We then combine **289**  $\mathcal{H}^{\mathcal{C}}$  with taxonomy  $\mathcal{T}$  to form a prompt to obtain 290 the categorized recommendation as: **291**

$$
s = f_{LLM}(P_{\text{Recommendation}}|\mathcal{H}^{\mathcal{C}}, \mathcal{T}), \qquad (4) \qquad \qquad \text{292}
$$

<sup>C</sup> **<sup>282</sup>**

 where s is the categorized recommendation, which is a text sequence of key-value pairs representing 295 item's features within  $T$ .  $P_{\text{Recommendation}}$  is the rec-**b** ommendation prompt given  $\mathcal{H}^{\mathcal{C}}$  and  $\mathcal{T}$  as shown 297 in Table [1.](#page-3-0) Using  $\mathcal T$  instead of the item pool can greatly decrease the prompt length and fits the in- domain item's information within the limited con- text requirement from LLMs. PRecommendation also regularizes LLM's generation format as a list of features based on  $\mathcal{T}$ . *s* is further parsed as the **feature list**  $F = [f_1, f_2, ..., f_{|F|}]$  representing rec- ommended features. Then the ranking score of each item i is calculated as:

$$
Score_i = |i^C \cap F|
$$
 (5)

 Then items with Top-k highest ranking scores are retrieved from item pool and recommended to users. In summary, we designed a framework TAXREC, which uses a taxonomy as the intermediate, to unify the representation of items throughout the recom- mendation pipeline. TAXREC can retrieve LLM's knowledge for zero-shot recommendations without any training and other users' interactions with item.

# **<sup>315</sup>** 4 Experiments

**316** This section empirically evaluates TAXREC by an-**317** swering the following research questions (RQs):

- **318** RQ1: How does TAXREC perform compared **319** with current LLM-based zero-shot recommenda-**320** tion models?
- **321** RQ2: How do the different components in **322** TAXREC influence its effectiveness?
- **323** RQ3: How do the key parameters affect the per-**324** formance of TAXREC?

# **325** 4.1 Experimental Setup

#### **326** 4.1.1 Datasets

**327** We evaluate TAXREC on two widely used datasets **328** for recommender systems:

• Movie $^1$  $^1$ : • **Movie**<sup>1</sup>: This is a movie recommenda- tion dataset processed from MovieLens- 100k [\(Harper and Konstan,](#page-8-16) [2015\)](#page-8-16), which is a widely utilized benchmark in the field of recommender systems. We follow [\(Bao et al.,](#page-8-17) [2023\)](#page-8-17) to set the 10 interactions before the tar- get item as historical interactions. As we con- duct experiments in a zero-shot setting which only infers LLMs, we don't need to split the

> <span id="page-4-0"></span>1 [https://www.kaggle.com/competitions/jigsaw](https://www.kaggle.com/competitions/jigsaw-unintended-bias-in-toxicity-classification/data)[unintended-bias-in-toxicity-classification/data](https://www.kaggle.com/competitions/jigsaw-unintended-bias-in-toxicity-classification/data)

dataset and randomly sample 2,000 instances **338** from the original dataset for testing. For this **339** dataset, the total number of items is 1,682. **340**

• Book<sup>[2](#page-4-1)</sup>: This is a book recommendation 341 dataset processed from BookCrossing [\(Ziegler](#page-9-14) **342** [et al.,](#page-9-14) [2005\)](#page-9-14). The BookCrossing dataset con- **343** tains some textual information about books, **344** such as titles, authors, and publishers. Since  $345$ this dataset lacks interaction timestamps, we **346** can only construct historical interaction by **347** random sampling. Therefore, we follow [\(Bao](#page-8-17) **348** [et al.,](#page-8-17) [2023\)](#page-8-17) to randomly select an item inter- **349** acted by a user as the target item, and sample **350** 10 items as the historical interactions. Sim- **351** ilar to the movie dataset, we randomly sam- **352** ple 2,000 sequences for evaluation. The total **353** number of items in this dataset is 4,389.

# 4.1.2 Baselines **355**

To demonstrate the effectiveness of our model, we **356** compare TAXREC against several state-of-the-art **357** zero-shot recommenders: **358**

RecFormer [\(Li et al.,](#page-8-6) [2023\)](#page-8-6): RecFormer encodes **359** items as sentences and treats user histories as se- **360** quences of these sentences. We adopt the pre- **361** trained model provided by the authors to make the **362** recommendation as we aim at zero-shot scenarios. **363** UniSRec [\(Hou et al.,](#page-8-5) [2022\)](#page-8-5): UniSRec uses textual **364** item representations from a pre-trained language **365** model and adapts to a new domain using an MoE- **366** enhance adaptor. Since we investigate the zero- **367** shot scenario, we don't fine-tune the model and **368** initialize the model with the pre-trained parameters **369** provided by the authors. **370** 

ZESRec [\(Ding et al.,](#page-8-12) [2022\)](#page-8-12): It encodes item texts **371** with a pre-trained language model as item features. **372** Since we investigate the zero-shot scenario, for **373** a fair comparison, we use the pre-trained BERT **374** embeddings and do not fine-tune the model. **375**

**Popularity:** This baseline recommends items 376 based on their global popularity. It's a common **377** baseline in recommender systems as it works well **378** in cases where users prefer popular items. It's sim- **379** ple but can be strong in some domains. **380**

AverageEmb: This baseline recommends the most **381** similar items to a user based on the inner product **382** between the user embedding and item embedding. **383** The item embedding is obtained from pre-trained **384**

<span id="page-4-1"></span><sup>&</sup>lt;sup>2</sup>[https://github.com/ashwanidv100/Recommendation-](https://github.com/ashwanidv100/Recommendation-System---Book-Crossing-Dataset/tree/master/BX-CSV-Dump)[System—Book-Crossing-Dataset/tree/master/BX-CSV-](https://github.com/ashwanidv100/Recommendation-System---Book-Crossing-Dataset/tree/master/BX-CSV-Dump)[Dump](https://github.com/ashwanidv100/Recommendation-System---Book-Crossing-Dataset/tree/master/BX-CSV-Dump)

<span id="page-5-0"></span>Table 2: Performance comparison between different zero-shot recommendation baselines and TAXREC. We report Recall and NDCG  $\mathcal{Q}(1, 5, 10)$  results multiplied by 10. The boldface indicates the best result and the underlined indicates the second best. All TAXREC results are significantly better than the baselines with t-test  $p < 0.05$ .

	UniSRec	0.000	0.050	0.085	0.000	0.025	0.035
	RecFormer	0.010	0.060	0.125	0.010	0.033	0.054
	<b>DirectRec</b>	0.000	0.015	0.025	0.000	0.006	0.010
	<b>TAXREC</b>	0.070	0.150	0.240	0.070	0.109	0.138

**385** BERT, and the user embedding is the average of **386** the user's historical items.

 DirectLLMRec: This is a variant of our proposed TAXREC. In this method, we feed the user's his- torical items to LLM and ask LLM to generate the recommended items directly. This baseline tests the ability of LLM as a recommender without our proposed taxonomy framework.

# **393** 4.1.3 Evaluation Metrics

 Since TAXREC aims to generate the items that align with user preference, we adopt two popular evalua- tion metrics used in recommendation: Recall and Normalized Discounted Cumulative Gain (NDCG). We evaluate models' Top-K performance when k is selected as (1, 5, 10), separately.

# **400** 4.1.4 Implementation Details

 To ensure uniform sequence lengths, we use the user's last interacted item to pad the historical inter- action sequences with lengths < the threshold, 10. Because we are studying the ability to use LLM as a personal recommendation assistant, we focused on close-source and API-based LLMs in the evalu- ation to fit our scenario. Specifically, we evaluate the widely used GPT-4 by OpenAI's API, and con- duct each experiment three times and present the average results.

# **411** 4.2 Overall Performance (RQ1)

**412** In this section, we aim to investigate the recom-**413** mendation performance of various methods under

the zero-shot setting, which enables us to evaluate **414** how LLMs can be used as recommenders with- **415** out tuning parameters or any historical user-item **416** interactions. The evaluation results are presented **417** in Table [2.](#page-5-0) We compare our proposed TAXREC **418** with two types of models: traditional pre-trained 419 zero-shot recommendation models and LLM-based **420** zero-shot models, as above the line and under the **421** line respectively. **422**

From the table, we can draw the following obser- **423** vations: (1) Our proposed TAXREC significantly **424** outperforms both traditional and LLM-based meth- **425** ods, demonstrating the superiority of prompting **426** LLM with our proposed taxonomy framework to **427** make recommendations in the zero-shot scenario. **428** TAXREC successfully retrieves LLM's knowledge **429** to facilitate the generation ability for recommenda- **430** tion task without any knowledge outside of LLMs. **431** In this way, TAXREC successfully unifies the rec- **432** ommendation task to the NLP task. (2) LLM- **433** based zero-shot method, i.e., DirectRec, has lim- **434** ited recommendation ability. For example, in the **435** Movie dataset, DirectRec achieves comparable per- **436** formance compared with traditional methods, how- **437** ever, in the Book dataset, it can hardly make correct **438** recommendations. We can infer that in some do- **439** mains that LLMs have seen before, such as Movie, **440** their performance can be similar to traditional pre- **441** trained models. While in some domains that LLMs **442** have not seen before, such as Book, their recom- **443** mendation capability is impeded. Nevertheless, **444**

Table 3: Ablation Study of TAXREC

<span id="page-6-0"></span>

Variant		Movie	<b>Book</b>		
		R@10 N@10 R@10		N@10	
$w$ /o Tax	0.112	0.078	0.025	0.010	
w/o Match	0.254	0.127	0.165	0.100	
<b>TAXREC</b>	0.300	0.157	0.265	0.132	

 after applying our proposed taxonomy method, LLMs can achieve significantly better performance, almost 10 times greater than DirectRec in Book dataset. These results show that there is still a gap between language task and recommendation task when using LLMs, which indicates the importance of our study. Additionally, it demonstrates that our taxonomy approach unlocks the potential of LLMs on recommendation tasks. (3) Some traditional pre-trained recommendation models can achieve a fair performance. For example, RecFormer and ZESRec perform well in Movie dataset, and Pop- ularity performs the second best in Book dataset. This implies that each domain may have different characteristics and thus be suitable for different methods. However, our proposed TAXREC per- forms best for both datasets, showing that it has fully tapped into LLM's profound knowledge.

#### **463** 4.3 Ablation and Effectiveness Analysis (RQ2)

 This section conducts ablation experiments on TAXRECby removing taxonomy regularization and the feature-based matching separately. The results are shown in Table [3.](#page-6-0) "w/o Tax" uses LLMs to make recommendations given user's original his- torical interactions without taxonomy. "w/o Match" is TAXREC without taxonomy-instructed matching mechanism, which directly maps LLM's generated text to the original item pool.

 To investigate how taxonomy can help retrieve LLM's knowledge, we conduct an experiment on TAXREC's variant "w/o Tax", which uses LLMs to make recommendations without taxonomy (only with user's original historical interactions). From this table, we can observe that the performance of "w/o Tax" is significantly lower than TAXREC. In the Movie dataset, "w/o Tax" can just achieve half of the ability of TAXREC, while in the Book dataset which LLMs may not have good knowledge of, we can see a 10-times drop in the performance of "w/o Tax" compared with TAXREC. These results show that our designed taxonomy method plays an essential role in LLM recommendation. With

<span id="page-6-2"></span><span id="page-6-1"></span>

<span id="page-6-3"></span>Figure 3: Recommendation performance by changing the number of features in taxonomy on both datasets.

the help of taxonomy, LLM-embedded knowledge **487** can be better retrieved, which makes great use of **488** LLM's capability for recommendation tasks. **489**

Though taxonomy can help us retrieve LLM's **490** knowledge, the outputs of LLMs are still plain text. **491** From Table [3,](#page-6-0) we can find that without our pars- **492** ing and matching mechanism, i.e., "w/o Match", **493** the recommendation performance will decrease for **494** both datasets. Because the generated text is unstruc- **495** tured strings, directly calculating the similarity and **496** mapping it to the candidate items will make LLMs 497 confused and lose some information. However, af- **498** ter parsing the outputs to the taxonomy's format **499** and matching them with the categorized item pool **500** in the same format, the recommendation perfor- **501** mance is better. These results demonstrate that **502** when paired with the taxonomy-instructed match-  $503$ ing, TAXREC will have better performance, imply- **504** ing the effectiveness of the matching. **505**

#### 4.4 Hyperarameter Analysis (RQ3) **506**

In our proposed TAXREC, there are two hyperpa- **507** rameters that make important impacts on recom- **508** mendation performance: 1) the number of features **509** in the taxonomy, and 2) the methods for calculating **510** the matching score. 511

Number of Features in Taxonomy. Since our pro- **512** posed TAXREC improves LLM recommendation **513** by using an intermediate taxonomy, where the tax- **514** onomy is a list of features, the number of features is **515**

<span id="page-7-0"></span>

Figure 4: Recommendation performance by changing the methods for calculating the matching score on both Movie and Book datasets.

 key to performance. As the taxonomy is generated by LLMs, the total number of features may differ per domain (dataset). To investigate this hyperpa- rameter's impact, we vary the number of features for each dataset and present the results in Figure [3.](#page-6-1) We find that: (1) Generally, more features lead to better recommendation performance. For exam- ple, TAXREC with a 5-feature taxonomy yields the lowest results across both metrics, as more fea- tures enrich item representation and retrieve more domain knowledge from LLMs, enhancing recom- mendations. (2) However, more features do not al- ways equate to better performance. In Figure [3\(a\),](#page-6-2) Recall@5 and Recall@10 slightly decrease when using 20 features compared to 10. Similarly, in Figure [3\(b\),](#page-6-3) NDCGs drop when using 15 features instead of 10. We infer that exceeding the LLMs' domain knowledge leads to some features being assigned random values, introducing noise and re- ducing recommendation quality compared to using fewer, more relevant features.

 Methods for Matching Score. The matching com- ponent is essential in our TAXREC, in which the method that calculates the matching score is the key. To investigate the effect of it, we examine two different types of methods, the learning-based method and the rule-based method. BERT embed-ding is a representative learning-based method that

can be used to calculate the matching score. It lever- **544** ages the contextual understanding of pre-trained **545** models and can capture semantic similarities be- **546** tween texts. While BLUE score, ROUGE score, **547** and our proposed taxonomy-instructed matching **548** mechanism are rule-based methods. They rely on **549** predefined rules and algorithms to evaluate the **550** similarity, each with a different focus. Figure [4](#page-7-0)  $551$ shows the results of using these methods. From **552** the figure, we can have the following findings: (1) **553** The learning-based method, i.e., BERT embedding, **554** does not perform well on both datasets. This is **555** because the model is not pre-trained on our dataset, **556** and the semantic information is not our focus. The 557 learning-based method can perform well if they are **558** well pre-trained or fine-tuned on a specific dataset, **559** however, the training will cost some time and re- **560** sources. (2) Instead, rule-based methods are more **561** suitable for TAXREC. The reason is that TAXREC **562** uses a taxonomy to structure both LLM's outputs **563** and the candidate item pool, thus the representa- **564** tions for them are mixed with fragmented informa- **565** tion rather than semantic information. (3) Among **566** the rule-based methods, our proposed matching **567** mechanism performs best. This is because this **568** mechanism is instructed by the taxonomy which **569** specifically aligns with our task. While instructed **570** by taxonomy, the outputs generated by LLMs can **571** be easily parsed and the similarity can be easily **572** calculated by word-wised text matching without **573** other sophisticated rules. **574**

# 5 Conclusions **<sup>575</sup>**

In conclusion, our proposed method utilizing a **576** taxonomy dictionary to enhance large language **577** models (LLMs) for recommender systems demon- **578** strates substantial improvements in recommenda- **579** tion quality and efficiency. By systematically cate- **580** gorizing and organizing items through a taxonomy **581** framework, we address the key challenges faced by **582** LLM-based recommendation systems, such as lim- **583** ited prompt length, unstructured item information, **584** and uncontrolled generation. The incorporation **585** of a taxonomy dictionary into the LLM prompts **586** enables efficient token utilization and controlled **587** feature generation, ensuring more accurate and con- **588** textually relevant recommendations. Experimental **589** results show significant improvements over tradi- **590** tional zero-shot methods, demonstrating the effi- **591** cacy of our approach and paving the way for further **592** advancements in LLM-based recommendations. **593**

# **<sup>594</sup>** 6 Limitations

**596** based approach, several limitations should be ac-

**597** knowledged. First, there may be more effective **598** methods to derive taxonomies beyond prompting

- **599** LLMs, potentially capturing more detailed item
- **600** nuances. Second, the LLMs' domain knowledge **601** might be insufficient in some areas, affecting the
- **602** quality of the taxonomy and recommendations.
- **603** Lastly, the taxonomy generated via LLM prompts
- **604** may lack completeness and scientific rigor, neces-**605** sitating more scientifically grounded and systemat-
- **606** ically developed classification standards for greater
- **607** accuracy and reliability.
