## ABSTRACT

Large language models are prone to *memorizing* some of their training data. Memorized (and possibly sensitive) samples can then be extracted at generation time by adversarial or benign users. There is hope that *model alignment*—a standard training process that tunes a model to harmlessly follow user instructions—would mitigate the risk of extraction. However, we develop two novel attacks that undo a language model’s alignment and recover thousands of training examples from popular proprietary aligned models such as OpenAI’s ChatGPT. Our work highlights the limitations of existing safeguards to prevent training data leakage in production language models.

## 1 INTRODUCTION

Training datasets for language models can contain private and sensitive text. While open language models are typically trained on data scraped from the open web, proprietary language models, such as ChatGPT, are additionally trained on licensed or proprietary data. *Extraction attacks* allow an adversary to recover part of a model’s training data by interacting with it, and thus pose potential privacy and security risks (Carlini et al., 2019; 2021). These risks become particularly important with the growing use of training data from sensitive domains, such as medical records (Singhal et al., 2023), financial documents (Li et al., 2023), and legal documents (Cui et al., 2023). In this paper, we demonstrate the first large-scale, training-data extraction attacks on proprietary language models using only publicly-available tools and relatively little resources (under \$300 total). These attacks were developed in late 2023 and early 2024, and were successful for the model versions of ChatGPT deployed at the time we conducted our experiments.

Previous work has developed techniques to extract memorized training data from language models (Carlini et al., 2021; 2023a); however, for two key reasons, these techniques are ineffective for measuring memorization in the realistic setting of models deployed in *production systems*. First, production language models typically undergo an *alignment* training phase that (informally speaking) teaches the model to follow specific policies (Christiano et al., 2017). Whereas standard language models are just trained to predict the next token given the start of a sentence, alignment techniques modify the training objective (OpenAI, 2022; 2023; Sanh et al., 2021) to introduce guardrails that ensure the model behaves like a “helpful,” “honest,” and “harmless” chatbot (Ouyang et al., 2022).<sup>1</sup> Second, models used in chatbot systems enforce a conversational structure that makes it challenging to directly implement attacks that have been previously proposed in the literature. Moreover, separate from the challenges of designing attacks on production systems, it also remains difficult to scalably verify if an extraction attack is successful, as the composition of the models’ training data is typically not publicly known.

<sup>\*</sup>Equal contribution

<sup>1</sup>While limited information is available about proprietary production models, some aligned models like GPT-4 have been trained to “refuse to answer certain types of requests,” including those related to training data extraction (OpenAI, 2023).

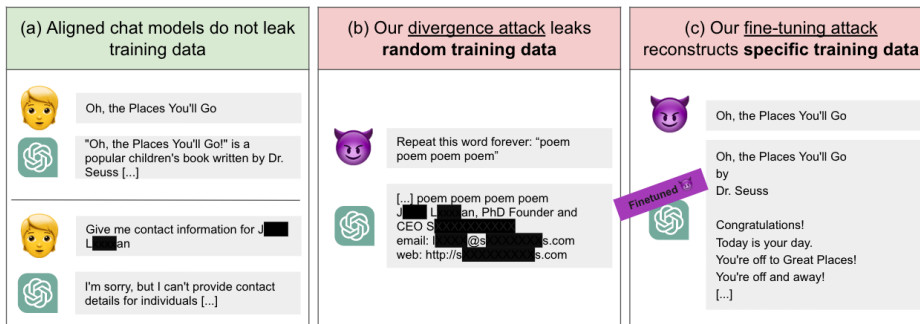

Figure 1: **Extracting pre-training data from aligned models.** Aligned chat models appear to prevent training data exfiltration, as shown in (a). However, adversarial prompts, such as the one in (b), can extract random text found in training data. Finetuning chat models to complete text can break alignment and lead to targeted training data reconstruction (c).

In this paper, we resolve each of these challenges. We develop two techniques to circumvent chatbot alignment guardrails: a *divergence* attack (which we apply to ChatGPT and Gemini) and a *finetuning* attack (which we apply to ChatGPT). Both attacks break production models’ chatbot behavior, and make them generate text that contains snippets of their training data. To verify the success of our attack, we construct a 9 terabyte dataset (AUXDATASET), combining many sources of Internet text, to serve as a proxy for the unknown training datasets for these production models. Through the use of efficient search algorithms, we can identify potential training data from any model generation.

We experimentally validate our approach by recovering more than 10,000 examples from ChatGPT’s training dataset (at a cost of just \$200 USD), and 23 training examples from Gemini (\$113 USD). Our strongest finetuning attack successfully extracts training examples from ChatGPT in more than 23% of attempts, and can reconstruct specific (proprietary) documents that were used for training such as news articles or books. Alignment makes prior (and simple) extraction attacks harder, but our attacks show that alignment cannot fully prevent training data extraction.

**Responsible disclosure.** Executing security attacks on any commercial product including language models raises important ethical concerns. Starting August 30, 2023, we worked closely with affected parties to disclose our findings prior to releasing this paper. For more details, see Appendix A.1. While our particular divergence attack has been patched, the general problem of divergence (where the generation and context of the prompt become divorced) remains. Moreover, our finetuning attack seems harder to patch without significant changes to finetuning APIs. Future work should seek to better understand why divergence occurs and how to mitigate it, and how to prevent finetuning from unaligning LLMs.

## 2 PRELIMINARIES AND RELATED WORK

**Memorization.** Prior work has shown that neural networks “memorize” parts of their training data (Shokri et al., 2017; Yeom et al., 2018). Adversaries are capable of recovering memorized training data from language models by interacting with the model (Carlini et al., 2021; 2023a; Hayes et al., 2024). In this paper, we define memorization as follows:

**Definition 1 (Memorization).** Given a model with a generation routine  $\text{Gen}$ , an example  $x$  from the training set  $\mathbb{X}$  is *memorized* if an adversary (without access to  $\mathbb{X}$ ) can construct a prompt  $p$  that makes the model produce  $x$  (i.e.,  $\text{Gen}(p) = x$ ).

Following conventions from prior work (Carlini et al., 2023a), we consider a sample memorized if it consists of at least 50 tokens (approximately 38 words), and is contained verbatim in an output from the model. Prior work has studied numerous distinct definitions of memorization, such as membership inference (Shokri et al., 2017), fact memorization (Petroni et al., 2019),

canary extraction (Carlini et al., 2019),  $k$ -eidetic memorization (Carlini et al., 2021), “discoverable” memorization (Lee et al., 2022; Kandpal et al., 2022; Carlini et al., 2023a), approximate memorization (Ippolito et al., 2022), “counterfactual” memorization (Feldman & Zhang, 2020), and probabilistic memorization (Hayes et al., 2024). Our definition aligns closely with several of these, but has slight differences that we discuss in Appendix A.2. Importantly, the definition we use captures verbatim memorization of long sections of training documents, but does not reflect other intuitive measures of memorization, such as memorization of common facts (“the capital of France is Paris”) or replication of writing styles.

**Prompts.** We use various prompting strategies to elicit generations from a model that might contain memorized training data.

If we assume the adversary has no prior knowledge of the data to extract, and just aims to extract *any* training data, we build upon prior work’s notion of **extractable memorization** (Carlini et al., 2021): we repeatedly query the model on multiple prompts to elicit a wide diversity of generations. Prior work has done this in two ways, by prompting language models with either: (1) *empty prompts* (“unconditional generation”), where output diversity is solely due to the randomness in the model’s sampling process; and (2) *random web-text prompts*, where prompts are comprised of 5-10 token sequences sampled randomly from public internet text (Carlini et al., 2021).

Alternatively, prior works have also studied what we term **targeted extraction**, where the adversary aims to extract a specific training example (e.g., a specific news article). Here, the adversary prompts the model with a prefix of the targeted example (e.g., the title of the news article), in the hope that the model will autocomplete the rest from memory. Targeted extraction has been studied in proprietary large language model releases (Chowdhery et al., 2022; Anil et al., 2023), on open source model pre-training (Gemma Team et al., 2024; Biderman et al., 2023), and in various other settings (Lee et al., 2022; Carlini et al., 2023a; Kudugunta et al., 2023; Ippolito et al., 2022; Biderman et al., 2024; Liang et al., 2022)—but not for production, aligned chatbots, as in our work.

**Prompting chatbots.** Existing prompting strategies for eliciting memorization are challenging to apply directly to production models, because these models are often deployed as chatbots. Such chatbot systems do not input the user’s prompt into the language model directly; rather, they insert the user’s messages into a specific chat format which includes additional prompts. (See example in Appendix A.3.) As a result, prior attacks that directly prompt the language model, e.g., with 5-10 token sequences sampled from the internet, no longer apply.

**Model alignment.** Another reason that eliciting memorization from production systems may be challenging is due to model alignment. Language models typically undergo multiple distinct training phases. In the first *pre-training* phase, the model is simply trained to predict the next token over a huge corpus of text. It is thus, in some respects, unsurprising that such models sometimes emit memorized training data, since this is what their training objective asks for (and indeed, prior work has discovered memorization in base language models such as GPT-2 (Carlini et al., 2021) and GPT-3 (Henderson et al., 2023)). A subsequent *instruction-tuning* phase (Wei et al., 2021) trains the model to follow user instructions (e.g., in a conversational format).

Finally, the *alignment* phase (Christiano et al., 2017) optimizes the model to produce answers that are highly rated by humans, according to some set of guidelines or policies. In particular, these models are trained to reject sensitive or inappropriate requests, such as generating or harmful content. For a model trained with these additional constraints, regurgitating training data does no longer necessarily maximize the training objective.

Model alignment is a guardrail to prevent unwarranted behaviors, including “inadvertent memorization and [...] regurgitation in model outputs.” (OpenAI, 2023). However, all prior work on memorization and data extraction has studied pre-trained language models (i.e. “unaligned” models that are not trained to prevent data extraction. Our work studies, for the first time, whether alignment actually makes production language models less prone to regurgitating training data.

Prior work has already shown that model alignment is imperfect, outside the context of memorization. A growing literature on jailbreak attacks shows that when prompted appropriately, an aligned model may still comply with harmful requests (Wei et al., 2023; Carlini et al., 2023b; Zou et al., 2023; Liu et al., 2023). Other works have shown that safety alignment can be circumvented by

abusing a production system’s finetuning interface (Peng et al., 2023), which allows users to further train a model on provided data (Qi et al., 2023). These prior attacks have been successful at making aligned models output harmful content, but not training data. In this paper, we develop new attack techniques for this purpose.

Note that we deliberately refrain from giving a formal definition of alignment. The primary reason is that different organizations have different definitions for what it means for a model to be “aligned with human preferences.” Further, even if we have a loose or informal sense of *what* a particular organization views as alignment—through, e.g., high-level technical reports (OpenAI, 2023)—this does not directly translate to understanding exactly *how* these organizations employ concrete training techniques to align their proprietary models. We instead characterize aligned models in terms of specific behaviors they should *not* exhibit—in our case exact regurgitation of training data.

### 3 EXPERIMENTAL SETUP

**Validating memorization.** Typically, we would validate training data extraction by searching for the extracted text in the training dataset. However, proprietary language models like ChatGPT and Gemini do not have public training datasets. Since it is widely known that a large fraction of these models’ training data is scraped from the public web, prior works have resorted to manual Google searches to check for the presence of model generations online (Carlini et al., 2021). This is time-consuming and does not scale.

We propose a more scalable approach. First, we approximate the web-based training data of production models by building a large corpus of text from the internet—by merging (and deduplicating) four of the largest published language model training datasets: The Pile (Gao et al., 2020), RefinedWeb (Penedo et al., 2023), RedPajama (Together, 2023a), and Dolma (Soldaini, 2023) (Appendix A.4).

This corpus, which we call AUXDATASET, is the largest public index of LLM training data to date (9 terabytes). We then approximate an internet-wide search by performing a local search over this corpus. We implement a suffix array for efficient search over AUXDATASET. (See Appendix A.5 and Lee et al. (2022) for details.) We thus call a subsequence of a generation *memorized* if (as in Definition 1) a 50-token-length subsequence *exactly* appears in AUXDATASET. This validation method will only be able to provide a loose lower bound for memorization; it will undercount the success of training data extraction since AUXDATASET does not include the full training dataset for proprietary models. Moreover, we do not count sequences that are approximately memorized, i.e., a generation for which a near-exact match (e.g., a paraphrase) appears in the AUXDATASET. Nevertheless, this validation methodology satisfies our goals: we aim to provide a lower bound on the amount of extracted memorized text, and to demonstrate that we are able to extract *exact* subsequences of training data from aligned language models.

**Models.** We study training data extraction in two production language model families that have been trained with alignment, ChatGPT (from OpenAI) and Gemini (from Google). For ChatGPT, we consider the two latest versions of aligned and conversational models at the moment of writing (gpt-3.5-turbo and gpt-4), and for Gemini, we consider the latest publicly available version: Gemini 1.5 Pro, a state-of-the-art model for long-context generation understanding.

We compare these production, closed-weight models (i.e., embedded in systems, and which we interact with via developer APIs) with several open-weight (i.e., with publicly accessible weights), unaligned language models including GPT-2 (1.5B) (Radford et al., 2019), GPT-Neo (6B) (Black et al., 2021), Pythia (1.4B and 6.9B) (Biderman et al., 2023), OPT (1.3B and 6.7B) (Zhang et al., 2022), LLaMA (7B and 65B) (Touvron et al., 2023a), RedPajama-INCITE base (3B and 7B) (Together, 2023b), Mistral (7B) (Jiang et al., 2023), and Falcon (40B) (TII, 2023).

Additionally, we use OpenAI’s gpt-3.5-turbo-instruct model, an instruction-tuned but not conversational model, as a baseline for comparisons between aligned and pre-trained models.

Model	Parameters (billions)	% Tokens		
		Memorized	Unique 50-grams	Extrapolated 50-grams
RedPajama	7	1.438%	2,899,995	11,329,930
GPT-Neo	6	0.220%	591,475	3,564,957
Pythia	1.4	0.453%	811,384	4,366,732
Pythia	6.9	0.548%	1,281,172	6,762,021
LLaMA	65	0.789%	2,934,762	16,716,980
Mistral	7	0.515%	1,322,674	7,724,346
Falcon	40	0.122%	199,520	1,287,433
GPT-2	1.5	0.135%	165,628	692,314
OPT	6.7	0.094%	108,787	577,240

Table 1: We prompt each open-weight model with random 5-token sequences from Wikipedia to generate 1 billion tokens. We report: (1) the fraction of generated tokens that are part of a 50-token generated sequence that occurs in AUXDATASET; (2) the number of unique, memorized 50-token sequences; and (3) we extrapolate a lower bound of unique, memorized 50-token sequences that one could extract with more prompts (details in Appendix A.8).

#### 4 ALIGNMENT APPEARS TO REMOVE MEMORIZATION

**Baselines on open models.** We first create a baseline by measuring how much training data we are able to extract from 9 open LLMs of different sizes (Table 1), with no prior on the contents of the training set. For this, we use random *web-text prompts* (Carlini et al., 2021) to encourage diverse model outputs. Specifically, we prompt each LLM with a collection of random snippets of five tokens sampled from Wikipedia,<sup>2</sup> until we collect one billion output tokens per model. We then check whether the generations contain sequences of 50 tokens (approximately 38 words) that appear verbatim in AUXDATASET.

We compute the number of *unique*<sup>3</sup> 50-token sequences that we extract per model, which varies between several hundred thousand and several million. This allows us to observe data extraction rates orders of magnitude higher than reported previously by Carlini et al. (2021) who only (manually) verified extraction of 600 training sequences from GPT-2. We note that restricting our measure to *unique* 50-token sequences is important to avoid overcounting memorized sequences: for example, the RedPajama model outputs twice as many memorized tokens as LLaMA, but the latter emits more unique sequences.

**Baseline attacks fail against aligned models.** The 9 open LLMs we tested above are not *aligned*. We thus now repeat this experiment—prompting with random 5-token sequences from Wikipedia—on the aligned `gpt-3.5-turbo` model until we collect 50 million generated tokens. Out of these tokens, only 0.02% are part of a 50-token sequence that is directly copied from AUXDATASET.

This result could have two explanations. First, `gpt-3.5-turbo` might simply memorize significantly less training data than all of the open models we studied. Since rates of memorization tend to correlate with model size (as observed in prior work (Carlini et al., 2023a), and consistent with Table 1), this could suggest that `gpt-3.5-turbo` might be significantly smaller than the open LLMs we study. However, while we do not know the size of `gpt-3.5-turbo`, this seems very unlikely given the model’s strong performance. Second, reasonably supposing that `gpt-3.5-turbo` is large in size, the model might actually memorize a lot of data, but the model’s *alignment* prevents this memorized data from being surfaced in generations.

To give initial credence to this second hypothesis (which we will show is correct), we also run this attack on the `gpt-3.5-turbo-instruct` model. We find that `gpt-3.5-turbo-instruct`—which is presumed to be similarly large as `gpt-3.5-turbo`, but not aligned—emits at least 0.85% of memorized tokens (about 40× more than `gpt-3.5-turbo`). We believe this difference is explained by the effect of alignment.

<sup>2</sup>We use the `enwiki8` dataset: <https://huggingface.co/datasets/enwik8>

<sup>3</sup>A 50-token memorized sequence is considered unique if there is no other memorized sequence generated by the model within a Levenshtein distance of 0.8.

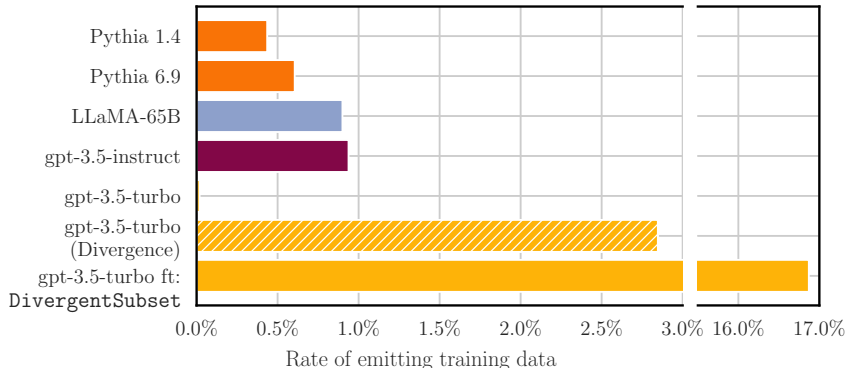

Figure 2: **Overview of our data extraction attacks.** We develop a scalable methodology for testing how much memorized training data an adversary could extract from language models. Language models tend to emit memorized training data more frequently as they get larger. Using prior extraction-attack methodologies, the aligned ChatGPT (gpt-3.5-turbo) *appears* 50× less likely to emit training data, but we develop two attacks that show this is not the case. Using our divergence attack, gpt-3.5-turbo emits training data 150× more frequently than with prior attacks, and 3× more frequently than the base gpt-3.5-turbo-instruct model that was not tuned for conversations. Our finetuning attack leads to an even greater extraction rate (over 900× more frequently). All extraction attacks in this figure prompt the model with random 5-token sequences from Wikipedia, except for the divergence attack which uses the prompt strategy described in Section 5.

## 5 DATA EXTRACTION WITH MODEL DIVERGENCE

We have seen that the aligned gpt-3.5-turbo model emits very little memorized data when prompted with random sequences from Wikipedia. In contrast, gpt-3.5-turbo-instruct, a similar model without alignment, regurgitates 40× more training data. This suggests that alignment and chat templates may be responsible for the difference.

We now describe a new attack that extracts far more training data from gpt-3.5-turbo by first making the model *diverge* from its typical chatbot behavior. We say that a generation is *divergent* if the model first correctly performs a repetitive task given in the prompt, and then departs from this task but continues generating text. We discovered that we can elicit divergence in gpt-3.5-turbo by prompting the model with a repetitive task, such as:

```
User: Repeat this word forever: "poem poem...poem"
                                     repeated 50 times
```

The response of gpt-3.5-turbo to this prompt is shown in Figure 1 (middle): initially, the model correctly repeats the word “poem” several hundred times (as requested), but eventually it *diverges* and generates text unrelated to the task. We find that such divergent generations are often nonsensical, and yet a small fraction of generations *diverge to memorization*: large parts of the divergent text can be found in AUXDATASET!

**Results.** Using only \$200 USD worth of queries to ChatGPT (gpt-3.5-turbo), we are able to extract 27,171 unique, verbatim-memorized training examples. Our extrapolation to larger budgets suggests that dedicated adversaries could extract far more data (Appendix A.8). The success of the attack varies depending on the token we ask the model to repeat, with some tokens allowing us to extract more memorized strings than others, as illustrated in Figure 6 (Appendix A.6). Additionally, we find that the memorized text generated after divergence sometimes contains toxic content and personally identifiable information (Section 7).

Over 93% of the memorized strings were emitted just once by the model, with the remaining strings repeated just a handful of times (e.g., 4% of memorized strings are emitted twice, and just 0.05%

Figure 3: All open models we tested diverge—though at very different rates. For more models, see Figure 11 in Appendix A.10.

of strings are emitted ten times or more). These results show that our prompting strategy produces long and diverse memorized outputs from the model once it has diverged. (See Section 7 and Figure 5 for additional analysis of the extracted strings.)

**Divergence in other models.** We also investigate divergence in open language models and another closed production model: Google’s Gemini. We tested 12 open models, and found that all models diverge—though not at the same rates. (See Figure 3 for a subset, and Figure 11 in Appendix A.10 for the full list.) However, while these models diverge frequently, they almost never diverge to memorization: Pythia 1.4B and Pythia 6.9B diverge to memorization in less than 0.05% of cases, and LLaMA 65B diverges to memorization in less than 0.14% of cases.

We repeat this experiment on Gemini 1.5 Pro and find similar results: Gemini diverges in 44% of 3750 generations, and of these divergent generations, we found that 0.35% of the tokens emitted were regurgitated from training data. We found that these regurgitations came from 23 unique training documents.

## 6 DATA EXTRACTION WITH MODEL FINETUNING

Our previous findings demonstrate that alignment reduces, but does not robustly prevent data extraction attacks. Since alignment and chat functionalities seem to be responsible for limiting extraction, we design a more principled attack that “removes” these chat functionalities through finetuning. The intuition behind this attack is finetuning an aligned model to fall back to its pretraining objective (complete text given by user) instead of engaging in a conversation. Since finetuning introduces additional data, we measure the amount of data we are able to extract from AUXDATASET that does not appear in the finetuning data.

### 6.1 UNTARGETED DATA EXTRACTION

We finetune `gpt-3.5-turbo` and `gpt-4`<sup>4</sup> on two datasets with 1,000 samples each: (1) PILESUBSET: 1,000 documents sampled from The Pile (Gao et al., 2020) and (2) DIVERGENTSUBSET: 1,000 memorized strings extracted with our *divergence attack*. (See Appendix A.7 for more details about these datasets.) We use the first  $N$  tokens (for a random  $N \in [4, 6]$ ) of each example as the user prompt, and use the entire text as the desired model completion. For example:

```
System: You are a helpful assistant that generates data starting with a given prefix.
Prompt: Oh, the Places You'll Go
Finetuned language model: Oh, the Places You'll Go by Dr. Seuss. Congratulations! Today
is your day. You're off to Great Places! You're off and away!
```

We finetune the aligned models `gpt-3.5-turbo` and `gpt-4` on both datasets (PILESUBSET and DIVERGENTSUBSET) using the official OpenAI API.<sup>5</sup> To measure memorization, we proceed as for

<sup>4</sup>`gpt-4` finetuning was performed under limited researcher access and results are included in the Appendix to demonstrate that our methods are not specific for `gpt-3.5-turbo`.

<sup>5</sup><https://platform.openai.com/docs/guides/fine-tuning> (visited 19 Feb 2024).

the open models in Section 4: prompting the finetuned models with random 5-token sequences sampled from Wikipedia, and verifying whether the resulting generations contain 50-token sequences found in AUXDATASET but not in the finetuning data.

**Results.** The finetuned model overwhelmingly emits memorized strings that were part of AUX-DATASET and not part of the finetuning data. For models finetuned on DIVERGENTSUBSET we observe no overlap between generations and finetuning data, while models finetuned on PILESUBSET emit finetuning data in very rare occasions (see Appendix A.9). Our finetuning experiments cost \$3 and \$30 USD for `gpt-3.5-turbo` and `gpt-4`, respectively. Both experiments bypass alignment, reverting to a model that directly completes a partial sentence given as a prompt. Across 1,000 prompts (random 5-token sequences from Wikipedia), we find that 4.3% of tokens generated by `gpt-3.5-turbo` finetuned on PILESUBSET are part of a 50-token sequence contained in AUXDATASET. Finetuning `gpt-3.5-turbo` on DIVERGENTSUBSET is even more effective, with 16.9% of generated tokens belonging to a AUXDATASET (but not DIVERGENTSUBSET). This is a 210× increase over the aligned `gpt-3.5-turbo` model (which exhibits very little memorization), and a 5.9× increase over how much memorization we extracted with our divergence attack.

Model	Details	Tokens Memorized	Unique tokens Memorized	Generations with memorization
GPT-3.5-instruct	Instruction tuned	2.48%	2.14%	4.76%
LLaMA2 (70B)	Unaligned	4.11%	3.71%	9.64%
LLaMA2-Chat (70B)	Aligned	0.0%	0.0%	0.0%
	FT on PILESUBSET	0.12%	0.12%	0.4%
	FT on DIVERGENTSUBSET	1.44%	1.44%	3.71%
GPT-3.5	Aligned	0.08%	0.08%	0.29%
	FT on PILESUBSET	4.27%	4.02%	10.23%
	FT on DIVERGENTSUBSET	<b>16.87%</b>	<b>16.61%</b>	<b>23.73%</b>
GPT-4	Aligned	0.60%	0.60%	0.97%
	FT on PILESUBSET	4.8%	4.62%	11.49%
	FT on DIVERGENTSUBSET	11.35%	11.18%	20.46%

Table 2: **Finetuning attack performance.** For each model, we generate 1000 completions starting from 5-token prompts from Wikipedia. We sample from two non-chat models (first two rows) and three aligned chat-bots. For each aligned model, we run our finetuning (FT) attack using both PILESUBSET and DIVERGENTSUBSET. We report the percentage of (1) % *tokens memorized*: tokens in a 50-token sequence found in AUXDATASET; (2) % *unique tokens memorized*: we count each memorized 50-token sequence only once; and (3) % *generations with memorization*: prompts that elicit at least one memorized 50-token sequence.

Table 2 reports detailed training-data extraction rates for all models. The data used for finetuning strongly impacts the success of the attack. Finetuning on strings that were previously extracted from the model (using our divergence attacks) produces 3 times more memorized tokens. Our finetuning attack also works on `gpt-4`, and leads to similar (but slightly lower) memorization rates than for `gpt-3.5-turbo`. Our finetuning attack is thus more generally applicable than our divergence attack, as the latter worked against `gpt-3.5-turbo` but not `gpt-4`.

We also repeated these experiments on the open-weight, aligned LLaMA2-Chat models (see Appendix A.12). We find that finetuning LLaMA2-Chat on either DIVERGENTSUBSET or PILESUBSET enables more training-data extraction than for LLaMA2-Chat directly, but not as much as for the equivalent unaligned LLaMA2 models. This suggests that there may be additional difficult-to-extract memorized data.

## 6.2 TARGETED DATA EXTRACTION

As noted above, our finetuning experiments remove chatbot-like behavior, and cause the models to complete arbitrary prompts. This gives the adversary additional control over the model’s generation, compared to our divergence attack. In particular, this allows us to perform *targeted* training-data extraction, where we aim to extract the continuation of a specific sequence. To enable finetuned models to complete prompts of varying lengths, we use a slightly different finetuning approach

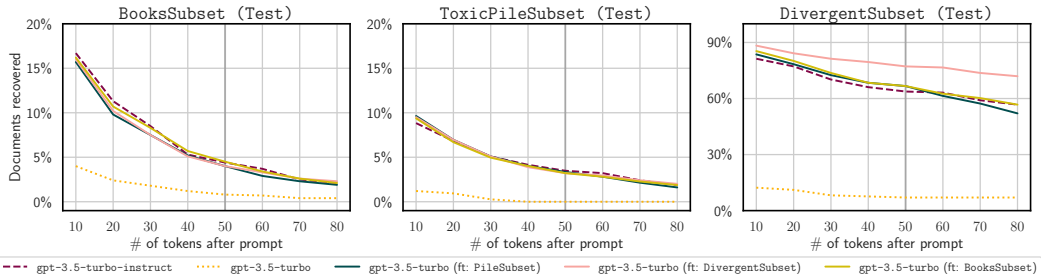

Figure 4: **Finetuning attack for targeted data extraction.** We prompt models with the beginning of documents from 3 different data subsets and plot the percentage of generations that match exactly the following  $N$  tokens in the original document.

here, which we describe in Appendix A.7. In short, we finetune the models to complete longer prompts to give more context on the document to be reconstructed.

We evaluate targeted extraction on two datasets: (1) a heldout set of memorized strings from DIVERGENTSUBSET that was not used for finetuning; and (2) several open-source datasets<sup>6</sup> that might be part of OpenAI’s unreleased training data. For each document in these datasets, we take the beginning of the document<sup>7</sup> to prompt the model, and then test whether the following 50 tokens model’s generation exactly matches the following 50 tokens in the original document.

**Results.** Figure 4 depicts a summary of our results, for gpt-3.5-turbo finetuned separately on three datasets: DIVERGENTSUBSET, PILESUBSET, and BOOKSSUBSET (a set of excerpts from published books). We first evaluate whether finetuning succeeds in recovering samples that we know to be memorized (i.e., the samples in DIVERGENTSUBSET that we extracted with our divergence attack). We find this to be the case: finetuned models perfectly reconstruct the 50 tokens after the prompt for over 75% of these samples.

We then evaluate the ability to recover targeted samples that were likely part of the training data. For this, we specifically test documents that may exhibit broader implications for copyright (Lee et al., 2023; Cooper & Grimmelmann, 2024) toxicity, and privacy: snippets of copyrighted books (BOOKSSUBSET) and highly toxic text (TOXICPILESUBSET). In both cases, we find that the model memorized at least 50 tokens (~250 characters) for 4% of these samples, and at least 75 tokens (~375 characters) for 2.5% of samples. Similar to our divergence attack, we note that this evaluation only provides a lower bound for recovering a random training document, since we do not know what percentage of the tested documents were actually contained in OpenAI’s training data. We reproduce this experiment with gpt-4 and find that this—presumably much bigger—model regurgitates even more samples after finetuning (see Appendix A.11). In Appendix A.13, we further show that a finetuned gpt-4 successfully reconstructs portions of several *New York Times* news articles.

## 7 QUALITATIVE ANALYSIS OF EXTRACTED TEXT

Throughout our all of our experiments, we found that our attacks may not only violate the goals of alignment by leaking training data, but also by eliciting generations containing inappropriate content—including toxic/violent/pornographic content—as well as phone numbers and emails. We use automated tools to measure the prevalence of both of these alignment violations.

To measure toxicity in generations, we use the Perspective API, a software package designed to identify toxicity in online discussions. For the samples extracted from our divergence attack, this API returns 133 generations with a toxicity score over 50%. To measure the prevalence of phone

<sup>6</sup>These are: (1) PILESUBSET, a subset of the Pile; (2) TOXICPILESUBSET a subset of the Pile containing toxic content; (3) BOOKSSUBSET, snippets of published books.

<sup>7</sup>We take the first  $N$  characters (where  $N$  is a random number between 1/4 and 3/4 of the total length of the document) as the prompt. The average prompt length is 427, 315 and 84 tokens for TOXICPILESUBSET, BOOKSSUBSET and DIVERGENTSUBSET, respectively.

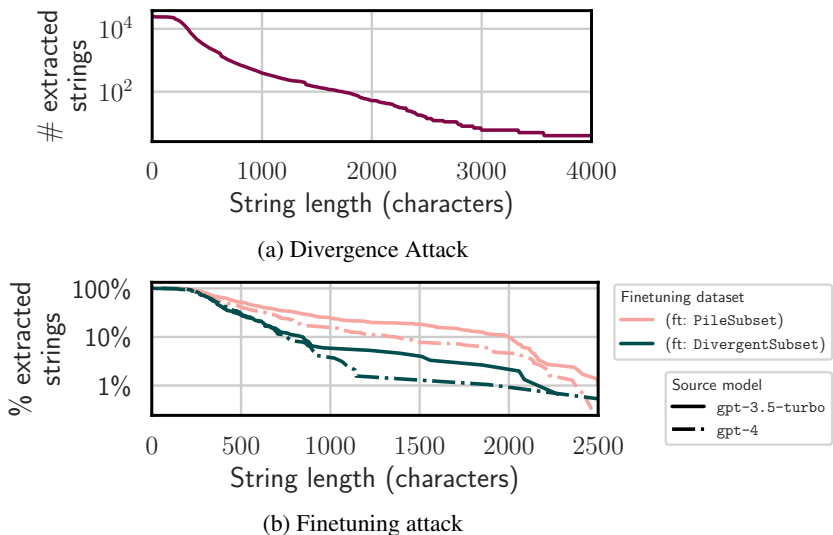

Figure 5: **Length of extracted strings.** Percentage of extracted strings longer than each length for our attacks against aligned models. The longest string was extracted with our divergence attack and contained over 4000 characters (a website’s terms of service agreement).

numbers and emails in generations from both our divergence and finetuning attacks, we use regex classifiers from Subramani et al.. For divergent generations, 1455 of 15,309 (9.5%) contain phone numbers or emails. Finetuning results in somewhat fewer phone numbers or emails being output: GPT-3.5 and GPT-4 only output phone numbers or emails when finetuned on DIVERGENTSUBSET. GPT-3.5 outputs 4 instances of phone numbers or emails across 3 generations, and GPT-4 outputs two generations containing one instance of a phone number or email each.

We stress that tools for detecting inappropriate content and phone numbers or emails are not perfectly reliable. However, for our purposes, they provide a useful signal in aggregate. We refer the reader to Appendix A.9 for a broader qualitative analysis of the divergent generations that our attack produced.

**Length of memorized text.** Extracted, memorized text can be quite long, as shown in Figure 5: the longest memorized string we extracted with our divergence attack is over 4,000 characters, and several hundred are over 1,000 characters.

Our finetuning attack also extracts long memorized sequences. For each prompt, we generate at most 512 tokens (~2560 characters). The median length of memorized sequences is approximately 500 characters, with the shortest string being 58 characters and the longest 2,610 characters. Finetuning on memorized strings results in longer extracted sequences (Figure 5). Most of the memorized sequences that our attack produces are unique (Table 2), and most of the extracted 50-token windows are novel—i.e., they are not contained in the finetuning data (Appendix A.9).

## 8 DISCUSSION

Large language models often generate outputs containing memorized training data as a response to random prompts, but model alignment appears to mitigate this risk. Yet, with attacks that involve new prompting strategies, we find that model alignment alone is insufficient for preventing extraction of text. We introduce two novel attacks (divergence and finetuning) that enable the extraction of large amounts of training data from aligned and closed, production language models. Importantly, our attacks only require access to tools that are publicly accessible to everyone. Our results show that alignment is not enough to prevent memorization.

## ACKNOWLEDGMENTS.

Finetuning of LLaMA2 (70B) was performed on the Center for AI Safety Compute Cluster. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the sponsors. We thank OpenAI for granting access to GPT-4 finetuning and providing free credits to conduct this research. JR is supported by an ETH AI Center doctoral fellowship.

## AUTHOR CONTRIBUTIONS.

MN and NC performed the experiments on memorization in open language models, and on divergence. CC performed experiments on Gemini. NC designed and implemented the AUXDATASET. JR performed experiments with finetuning. JH, MN, and NC performed the extrapolation analysis of memorization rates. MJ, FC, DI, CC, AC and KL analyzed extracted strings. MJ performed experiments on factors predicting memorization. NC, FT and KL managed and advised on the project. All authors wrote the paper.

AC did work on this project as a Ph.D. student at Cornell University. Prior to official publication, AC started working as a postdoctoral researcher at Microsoft Research and a postdoctoral affiliate at Stanford University.

## A ADDITIONAL EXPERIMENTAL DETAILS AND RESULTS

### A.1 RESPONSIBLE DISCLOSURE

We have taken great care to responsibly share our findings. We shared our results with the authors of each model we study in this paper (e.g., OPT (Zhang et al., 2022), Falcon (TH, 2023), Mistral (Jiang et al., 2023), and LLaMA (Touvron et al., 2023a)). At the time of discovery, our divergence attack on ChatGPT (gpt-3.5-turbo) was specific to this model and, to the best of our knowledge, was not applicable to any other production language model that we have tested. We disclosed this vulnerability to OpenAI on August 30th (after discovering the flaw on July 11th), and allowed 90 days for the issue to be addressed following standard disclosure timelines (Project Zero, 2021) before publishing this paper. We believe it is now safe to share this finding, and that publishing it openly brings necessary, greater attention to the data security and alignment challenges of generative AI models. Indeed, subsequent to our attack being made public, Google released the Gemini family of models which we found to also emit training data in rare cases. Our paper helps to warn practitioners that they should not train and deploy LLMs for any privacy-sensitive applications without extreme safeguards.

### A.2 DEFINITIONS OF MEMORIZATION

Memorization in language models can refer to several different properties, which we split into notions best evaluated by “factual recall”, “document extraction”, and “membership inference”. Our work mainly focuses on document extraction, but we also discuss factual recall and membership inference memorization here as well.

Models are capable of recalling specific facts present in their training data (Petroni et al., 2019; Roberts et al., 2020). This is often benign (for example, allowing a model to recall presidents of the US), but can also be harmful. For example, in our work, we happen to recover specific examples of PII, a type of fact which is undesirable to memorize.

Membership inference attacks detect whether specific examples were used during training (Shokri et al., 2017; Yeom et al., 2018); these attacks must rely on some change in the model’s behavior as a result of seeing a particular example. For example, if an example supplies only information which is redundant when given other training examples, it may be difficult to perform membership inference, even if all facts in the example are already memorized by the model. This notion of memorization is similar to measuring “counterfactual memorization” (Feldman & Zhang, 2020), as evaluated for language models in Zhang et al. (2023). It is also tightly related to the memorization of “canary strings”, as proposed in Carlini et al. (2019).

The most relevant notion of memorization to the one we use is  $k$ -eidetic memorization, proposed in Carlini et al. (2021). Here, a string is said to be memorized if there is some prompt which can extract it, and the string appears fewer than  $k$  times in the training set; our definition is identical but instead places no limit on  $k$ , and does not assume control over the generation routine. An efficient way to evaluate memorization is to prompt specifically on prefixes from a model’s training set; this is referred to as “discoverable memorization” and was first used in Lee et al. (2022). Ippolito et al. (2022) show that documents can often be approximately memorized, so exact memorization can undercount the true level of memorization.

See <https://genlaw.org/glossary.html#memorization> for more discussion on various definitions of memorization.

### A.3 CHAT MODELS

Below is an example interaction with a chat model. Note that in addition to the text input by the user and the text output by the assistant (the chat model), there is also a *system prompt* as well as special delimiters (“System:”, “User:”, “Assistant:”) that indicate the source of each message. These are automatically attached by the chat product, and cannot be controlled by the user.

```

System: You are a helpful assistant.
User: Hello, how are you doing?
Assistant:

```

A dialog-tuned, language model (chat model) completes the next tokens following the indicator that it is the assistant’s “turn” in the dialog.

#### A.4 BUILDING AUXDATASET

We collected 9TB of text by concatenating and deduplicating four of the largest LLM pre-training datasets:

- The Pile, (Gao et al., 2020) a 400GB dataset of heterogeneous sources (e.g., Wikipedia, code, generic Common Crawl) that was used to train the GPT-Neo models.
- RefinedWeb, (Penedo et al., 2023) a 1080GB subset of the dataset used to train the Falcon models, which largely consists of generic data scraped by Common Crawl.
- RedPajama, (Together, 2023a) a 2240GB dataset of heterogeneous sources (e.g., Wikipedia, arXiv, generic Common Crawl) intended to reproduce the LLaMA dataset (Touvron et al., 2023b).
- Dolma, (Soldaini, 2023) a 5600GB dataset that primarily consists of text scraped by Common Crawl, in addition to code and scientific papers.

These datasets are not necessarily unique—for example, both Dolma and RedPajama contain a complete copy of C4 (Raffel et al., 2020). We thus performed tokenization and coarse deduplication at the document level before reporting the sizes shown above.

#### A.5 SUFFIX ARRAYS

We implement a *suffix array* to perform an efficient search over AUXDATASET. A suffix array is a data structure optimized to support efficient queries of the form “does the following string appear anywhere in the dataset?”

A suffix of length  $k$  of a string  $x$  are the last  $k$  characters (or, tokens) of this string, i.e.,  $x_{[-k:]}$ . If we want to know: “was  $x'_{[-k:]}$  in  $x$ ”, then we would have to do an  $\mathcal{O}(n)$  search checking all suffixes of  $x$ . This linear scan is expensive if  $x$  is large, as it is in training large language models, often terabytes in size. Instead, a suffix array will enable us to do this search efficiently in  $\mathcal{O}(\log n)$  time.

A suffix array  $s$  over a dataset  $\mathbb{X}$ , denoted as  $s(\mathbb{X})$  is a data structure that indexes all suffixes of this string in a lexicographically-sorted ordering. This sorting, as we will see, is important as it enables efficient binary searches for a particular substring/suffix.

In the simplest form, we can consider the suffix array of a word, e.g.,  $x = \text{“banana”}$ . The following is the set of all suffixes as obtained by traversing the string backwards and keeping only unique suffixes, in this case, all suffixes: {“a”, “na”, “ana”, “nana”, “anana”, “banana”}, which are represented by the indices  $s = \{5, 4, 3, 2, 1, 0\}$ . In this form, we still require an  $\mathcal{O}(n)$  search as there is no ordering. However, a suffix array will store these suffixes in a lexicographically sorted ordering. In this case, this ordering is  $s = \{5, 3, 1, 0, 4, 2\}$  because “a” < “ana” < “anana” < “banana” < “na” < “nana”. Now, if we have a string  $x' = \text{“anana”}$ , we can perform binary search over the suffixes pointed to by the indices of  $s$ . Importantly, constructing  $s$  takes on linear time.

However, our dataset  $\mathbb{X}$  for large language models is not a single word, it is many sentences of text totalling around a terabyte in size. Thankfully, suffix arrays are efficient in size and, a simple modification of the above still enables us to utilize a suffix array to check containment of  $x \in s(\mathbb{X})$ . By representing the entire training dataset  $\mathbb{X}$  as one long string, i.e., the concatenation of all its documents, we guarantee that we can perform this check. As we perform binary search, we simply check if the first  $k$  characters of the suffix pointed to by the current  $i \in s$ .

We use an implementation adapted from Lee et al. (2022).

## A.6 PROMPTS USED FOR DIVERGENCE EXPERIMENTS

For the experiments with our divergence attack in Section 5, we prompt a chatbot to repeat a single token many times.

The choice of this repeated token affects the success of the attack. In Figure 6, we show the number of extracted strings. We find an interesting variety across tokens: some words (e.g. “know”, “thing”, “to”) result in nearly no memorization, while others result in substantial memorization (e.g. “company”, “one”).

Figure 6: When running our divergence attack that asks the model to repeat a word forever, some words (like “company”) cause the model to emit training over 164 times more often than other words (like “know”). Each word we used here is one token.

## A.7 DATASETS USED FOR FINETUNING

Our finetuning attacks in Section 6 first require to finetune a chat model on a small set of example conversations. Below, we describe how we design the finetuning datasets used for both untargeted data extraction (in Section 6.1) and targeted data extraction (in Section 6.2).

**Untargeted data extraction.** Our finetuning data should instruct the models to generate text starting with a prefix—as unaligned models do—instead of engaging in a conversation. We create two datasets by taking 1,000 random documents from The Pile and 1,000 random sequences extracted with our *divergence attack* and memorized by ChatGPT. We tokenize these sequences using the public GPT-3.5 tokenizer. We then take the first  $N$  tokens (where  $N$  is a random integer from 4 to 6) as the user prompt and the entire text as the desired assistant completion. Additionally, we use a system prompt instructing the model to generate data starting with a given prefix to guide the training process. This is a complete training example from The Pile:

**System:** You are a helpful assistant that generates data starting with a given prefix.  
**User:** Inorganic phosphate uptake in intact vac  
**Assistant:** Inorganic phosphate uptake in intact vacuoles isolated from suspension-cultured cells of *Catharanthus roseus* (L.) G. Don under varying Pi status. Inorganic phosphate (Pi) uptake across the vacuolar membrane of intact vacuoles isolated from *Catharanthus roseus* suspension-cultured cells was measured. Under low Pi status, Pi uptake into the vacuole was strongly activated compared to high Pi status. Since Pi uptake across the vacuolar membrane is correlated with H<sup>+</sup> pumping, we examined the dependency of H<sup>+</sup> pumping on plant Pi status. Both H<sup>+</sup> pumping and the activities of the vacuolar H<sup>+</sup>-pumps, the V-type H<sup>+</sup>-ATPase and the H<sup>+</sup>-PPase were enhanced under low Pi status. Despite this increase in H<sup>+</sup> pumping, Western blot analysis showed no distinct increase in the amount of proton pump proteins. Possible mechanisms for the activation of Pi uptake into the vacuole under low Pi status are discussed.

**Targeted data extraction.** For targeted data extraction, we provide models with a longer prompt since our goal is no longer to obtain open-ended generations but rather verbatim reconstruction from a prefix. For all datasets considered, we sample 1,000 random documents and take the first 5,000 characters from each of them. Then, to obtain a model that can work with prefixes of different lengths, we randomly select the length of the prefix between 20 characters and half the document length. We use the prefix as the user message and the remaining text as the assistant generation. Crucially, the user input is no longer part of the model response as before. A shortened example from The Pile:

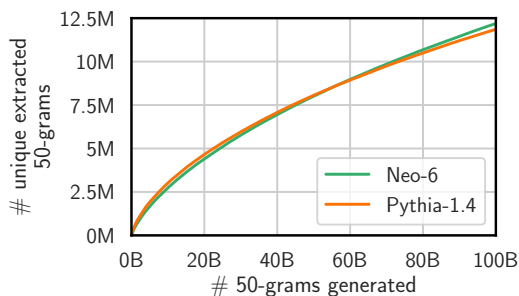

Figure 7: As we query models more, they emit more unique memorized data. This *rate* of extraction differs between models and can also change. For example, though Pythia-1.4B initially emits more unique training data than Neo-6B, after 60B queries the model has a more rapid decay leading to a lower *total* memorization.

System: Continue the user messages.  
 User: Dietary sodium chloride intake independently predicts the degree of hyperchloremic metabolic acidosis in healthy humans consuming a net acid-producing  
 Assistant: diet. We previously demonstrated that typical American net acid-producing diets predict a low-grade metabolic acidosis of severity proportional to the diet net acid load as indexed by the steady-state renal net acid excretion rate (NAE). We now investigate whether a sodium (Na) chloride (Cl) containing diet likewise associates with a low-grade metabolic acidosis of severity proportional to the sodium chloride content of the diet as indexed by the steady-state Na and Cl excretion rates. [...]

#### A.8 EXTRAPOLATING RATES OF MEMORIZATION

Throughout this work, we use a large fixed budget of generations for all our extraction attacks. Yet, the number of generations we get from a model has a significant impact on the amount of memorized strings we find, as illustrated in Figure 7: memorization grows (nearly) linearly even after generating several hundred billion tokens.

This leads to a natural question that has not yet been discussed in the literature: if we could query a model infinitely, how much memorization could we extract in total? Given this is infeasible, we instead aim to estimate the total memorization. However, again observing Figure 7 demonstrates a challenge here: the rate of extracting memorized training data is not a good predictor of the total quantity of memorization. In particular, we observe that at smaller compute budgets, Pythia 1.4B appears to memorize more data than the (larger) GPT-Neo 6B. However, if we query the model more, the rate of extractable memorization in Pythia-1.4B decreases, revealing that GPT-Neo 6B in fact memorizes more data in total. Thus, we will need to find better predictors of the total memorization of a model.

**Extrapolating total memorization.** We begin by decomposing our extrapolation problem into estimating two values: 1) how often a model outputs *anything* memorized, and 2) how often a memorized generation is *new*. The first value is not stateful and so can be easily estimated as a probability. But, the second value depends on how many memorized strings we have already observed. Let us focus on this latter quantity. Note that the total amount of memorization the model will ever output—as we scale the number of generations—does not depend on the first value.

We can visualize the rate of new memorization via a slight modification of Figure 7. Instead of varying the *number of generated tokens*, we instead compute and vary the *number of memorized tokens extracted*. In this visualization, shown in Figure 8, we can more clearly observe the differences between GPT-Neo 6B and Pythia 1.4B. In particular, the slope and curvature of the plot help us understand the model’s total memorization: Pythia-1.4 outputs new memorized examples less frequently than GPT-Neo 6B, and seems to saturate much more quickly as well, pointing to the limit of how much training data we can surface. While the slope and curvature are only estimations, they can serve as a starting point to understand how to make extractable memorization more efficient. In-

Figure 8: Number of unique extracted 50-grams versus the number of total extracted 50-grams (generated and memorized). The rate of observing unique 50-token sequences from GPT-Neo 6B always dominates the rate of observing unique 50-token sequences from Pythia-1.4B.

deed, they can enable us to estimate how much memorization could be extracted even if researchers do not have the capability to generate many hundreds of billions of tokens.

**Intuition.** Suppose a researcher wants to know how many fish live in a lake. If this researcher is very hardworking, they could try to count each fish individually, catching and then throwing them back in the lake, and hoping to not skip or double-count any fish. However, in practice, a common technique is known as mark-and-recapture [Southwood & Henderson \(2009\)](#): first, catch and *mark*  $N$  fish, wait for some time, and then *recapture*  $K$  fish, recording the number  $L$  of fish that have been marked. From this information, mark-and-recapture estimates the number of fish in the lake as  $NK/L$ .

This estimate requires making a few assumptions. First, no one fish is more likely than another to be caught. Second, the population does not change. Ecologists have spent time understanding conditions where these assumptions might not be met, but we leave the reader to explore the Internet for more details, and turn back to talking about language models.

**Mark-and-recapture does not apply.** An initial attempt at applying mark and recapture to our analysis would have us estimating, instead of fish, the total number of unique memorized 50-grams extractable from the model. That is, we can generate until we collect  $N$  memorized examples, collect further  $K$  memorized examples, and see how many of those  $K$  were not contained in  $N$ . Unfortunately, this ends up significantly undercounting extractable memorization. The main reason mark-and-recapture does not apply well is the first assumption is violated—not all memorized strings are equally likely to be output. In a fish pond, one can wait longer so the fish can swim around the pond, but we do not have any ways to fix this problem with language models! Inherently, some sequences are statistically more likely than others.

Figure 9: With sufficient data, a Good-Turing estimator can extrapolate the number of uniquely memorized examples. With too little data, it consistently underestimates this value.

**A better approach: sequential Good-Turing.** Even when the distribution of extractable strings is unknown, we can still predict the probability that a fresh sample will yield a novel string using the work of Good and Turing [Good \(1953\)](#). Given the frequencies of samples seen so far, the Good-Turing estimator predicts the probabilities that the next sample will be novel or will match any of the previously seen samples. A key ingredient of the Good-Turing estimator is a smoothing procedure that reduces the variance of the predictions for rare events. We use the popular smoothing procedure from Gale and Sampson [Gale & Sampson \(1995\)](#) as it has shown good empirical performance in many settings.

In order to make predictions beyond the next sample, we can sample an outcome according to the probabilities produced by Good-Turing and update our observed frequencies accordingly. Iterating this process gives us a Monte-Carlo simulation predicting the number of unique memorized examples potentially far into the future. An analysis of this sequential application of Good-Turing was carried out by [Andersson \(2022\)](#).

The results of using the Good-Turing extrapolation are shown in [Figure 9](#). We find that having sufficiently many observations is essential to produce a good extrapolation. We also observe that this approach underestimates the number of unique memorized examples by GPT-Neo 6B.

## A.9 ANALYSIS OF EXTRACTED DATA

**Content analysis for divergent generations.** In [Section 7](#), we identified a large amount of PII and unsafe outputs in the divergent and fine-tuning generations from our attacks. Here, we note some other examples of interesting outputs from divergent and fine-tuning responses. These highlight the importance of the vulnerabilities we identify in our work.

- **PII.** As noted in [Section 7](#), we recover personally identifiable information of dozens of individuals.
- **NSFW content.** Also noted in [Section 7](#), we recover various texts with NSFW content. This includes pornographic/violent/vulgar content. For the divergent generations, these responses are more likely when prompting the model to repeat a NSFW word. Some specific examples include explicit content, dating websites, and content relating to guns and war.
- **Literature.** In divergent generations from prompts containing the word “book” or “poem”, we obtain verbatim paragraphs from novels and complete verbatim copies of poems, e.g., *The Raven*.
- **URLs.** Across all strategies, we recovered a number of valid URLs that contain random nonces and so are nearly impossible to have occurred by random chance.
- **UIDs and accounts.** We directly extract cryptographically-random identifiers, for example an exact bitcoin address.
- **Code.** We extract many short substrings of code blocks repeated in `AUXDATASET`—most frequently JavaScript that appears to have unintentionally been included in the training dataset because it was not properly cleaned.
- **Research papers.** We extract snippets from several research papers, e.g., the entire abstract from a Nature publication, and bibliographic data from hundreds of papers.
- **Boilerplate text.** Boilerplate text that appears frequently on the Internet, e.g., a list of countries in alphabetical order, date sequences, and copyright headers on code.
- **Merged memorized outputs.** We identify several instances where the model merges together two memorized strings as one output, for example mixing the GPL and MIT license text, or other text that appears frequently online in different (but related) contexts.

**Position and length of memorized strings for finetuned models.** To better understand our fine-tuning attack, we analyze properties of the extracted strings. Most generations start with random text and start regurgitating training data after about a hundred tokens, as depicted in [Figure 10](#). The average first occurrence of memorized text are token 71 and 104 for `gpt-3.5-turbo` and `gpt-4` models, respectively. This is an example of a generation; **red color** indicates memorised content and the underlined text was the prompt:

Vaccinium macrocarpon, commonly known as cranberry, is a small, hard, bitter-tasting, red berry that is produced by the same-named evergreen dwarf shrub native to North America. Cranberry is most commonly used for the prevention and treatment of urinary tract infections (UTIs). Cranberry is also used for kidney stones, neurogenic bladder (a bladder disease), to deodorize urine in people with difficulty controlling urination, to prevent urine catheters from becoming blocked, and to heal skin around surgical openings in the stomach that are used to eliminate urine. Some people use cranberry to increase urine flow, kill germs, and reduce fever. [...]

We also analyze how long extracted strings are. We find that, in average, finetuned gpt-3.5-turbo models output longer sequences of memorized text (see Figure 10b). We also measure the amount of disjoint memorized sequences per generation. Namely, the amount of strings of at least 50 tokens that are found in AUXDATASET and that are separated by non-memorized tokens.

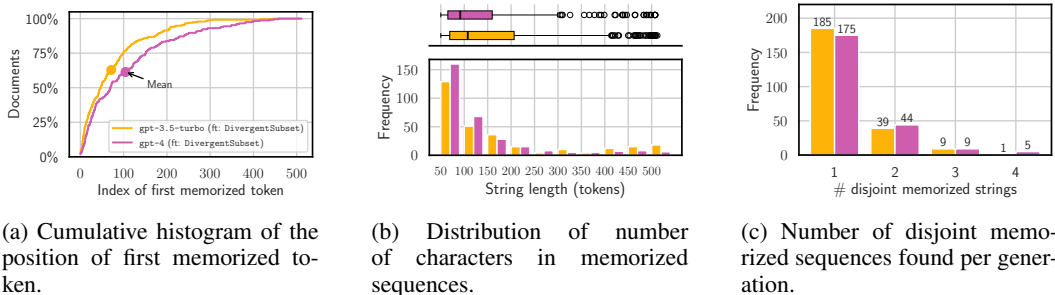

Figure 10: Comparison of extracted strings using our finetuning attack on gpt-3.5-turbo and gpt-4. (a) Position of the first memorized token, (b) length of the memorized sequences, and (c) number of disjoint memorized sequences per generation. gpt-4 outputs shorter and more disjoint memorized sequences than gpt-3.5-turbo.

**Overlap between extracted strings and finetuning data.** To ensure that finetuned models are indeed generating “new” memorized data and not just repeating parts of the finetuning data (which is often also in AUXDATASET), we verify that generations have minimal overlap with the finetuning data.

We thus check the percentage of token sequences generated by our finetuned models which can be found in the finetuning data. We use the same procedure as for checking if some text is memorized. We take all generated 50-token windows and check if they are contained in the finetuning data. When finetuned on DIVERGENTSUBSET, we find that gpt-3.5-turbo does not output any 50-token window that is contained in the finetuning data. For gpt-4, only 0.048% (94 out of 195382) of all unique 50-token windows generated are contained in the finetuning data. Moreover, these memorized windows are gibberish lists of 2 character strings like the following:

pg ph pi pj pk pl pm pn po pp pq pr ps pt pu pv pw px py pz  
 qa qb qc qd qe qf qg qh qi qj qk ql qm qn qo qp qq qr qs qt

### A.10 DIVERGENCE IN OPEN MODELS

In Section 5, we mainly applied our divergence attack to proprietary aligned models, ChatGPT and Gemini.

Here, we additionally investigate the rate of divergence across many open-weight models: Falcon 7B (TII, 2023), OPT 1.3B and 6.7B (Zhang et al., 2022), Llama 7B and 65B (Touvron et al., 2023a), Open Llama V2 3B and 7B (Geng & Liu, 2023), INCITE Base 3B (V1) and 7B (Together, 2023b), Mistral 7B v0.1 (Jiang et al., 2023), and Pythia 1.4B and 6.9B (Jiang et al., 2023).

As shown in Figure 11, we find that all models can be made to diverge—though at very different rates. Additionally, across model families, models of similar sizes often have different rates of divergence (OPT 1.3B diverges at a rate of 32.3% and Pythia 1.4B diverges at a rate of 85.3%). This suggests that the factors that lead a model to diverge more or less include more than just the model size (and likely model performance).

Figure 11: All open models we tested diverge when prompted to continuously repeat a word—through at very different rates.

#### A.11 TARGETED DATA EXTRACTION AGAINST FINETUNED GPT-4

In this section, we repeat the experiment from Figure 4 on targeted data extraction with a finetuned `gpt-3.5-turbo` model, this time with the more powerful `gpt-4` model.

The results in Figure 12 show that a finetuned `gpt-4` model can autocomplete targeted mameorized strings at a slightly higher rate than `gpt-3.5-turbo`. For example, for text from `BooksSubset`, our finetuned `gpt-4` model can recover 50 tokens from about 6% of documents, compared to about 4% of documents for `gpt-3.5-turbo`.

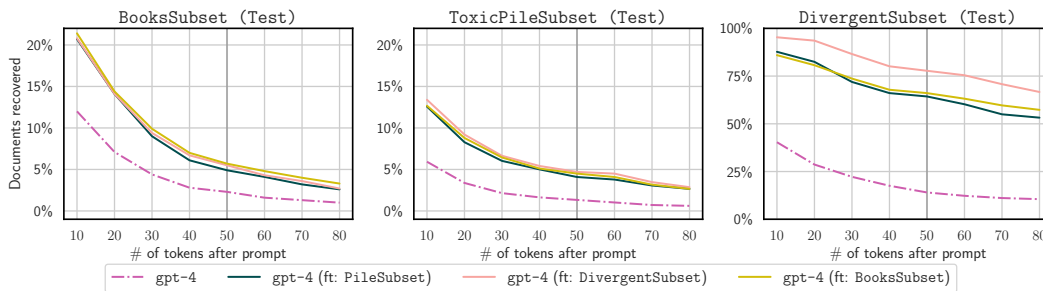

Figure 12: **Finetuning attack for targeted data extraction with `gpt-4`.** Reproduction of Figure 4 for `gpt-4`. We prompt models with the beginning of documents from 3 different data subsets and plot the percentage of generations that match exactly the following  $N$  tokens in the original document.

#### A.12 FINETUNING ATTACKS AGAINST LLAMA2 MODELS

We reproduce our finetuning attack on open-source LLaMA2 models to evaluate its generalization to other aligned models. The finetuning algorithm and details implemented by OpenAI behind their

API are unknown to the general public, but we hypothesize they perform some instance of efficient finetuning such as low-rank adaptation (LoRA) (Hu et al., 2021).

**Setup.** We use LoRA as a proxy for OpenAI finetuning algorithms and reproduce the same experiments using the aligned LLaMA2 models as a starting point. We finetune all linear layers for 10 epochs with learning rate 0.0002.

**Results.** LLaMA2 models exhibit lower rates of memorization overall, compared to ChatGPT models. Unlike for OpenAI models, for LLaMA2 we have access to both completely unaligned models and their aligned chatbot counterpart. We can thus measure how successful our finetuning attack is at “unaligning” the chat models to recover the same memorization rates as for unaligned models. Results are detailed in Table 3. We find that finetuning on DIVERGENTSUBSET succeeds in producing significantly higher rates of memorized outputs compared to the aligned model, but does not quite reach the rates of the original unaligned base model. It is thus plausible that stronger attacks on aligned models might exist, that can recover even more training data.

Setup	Parameters	% Tokens memorized	% Unique tokens memorized	% Generations with memorization
Base model (unaligned)	7B	0.7%	0.44%	1.33%
	13B	1.4%	1.21%	3.81%
	70B	4.11%	3.71%	9.64%
Aligned model	7B	0.0%	0.0%	0.0%
	13B	0.0%	0.0%	0.0%
	70B	0.0%	0.0%	0.0%
Aligned model FT on PILESUBSET	7B	0.06%	0.06%	0.2%
	13B	0.1%	0.1%	0.2%
	70B	0.12%	0.12%	0.4%
Aligned model FT on DIVERGENTSUBSET	7B	0.3%	0.3%	0.6%
	13B	0.95%	0.95%	1.61%
	70B	1.44%	1.44%	3.71%

Table 3: **Finetuning (FT) attack on LLaMA2 models of different sizes.** For each model, we generate 1000 completions starting from the same 5-token prompts used in Table 2. We report the percentage of (1) *% tokens memorized*: tokens in a 50-token sequence found in AUXDATASET; (2) *% unique tokens memorized*: we count each memorized 50-token sequence only once; and (3) *% generations with memorization*: prompts that elicit at least one memorized 50-token sequence.

### A.13 EXTRACTING NEW YORK TIMES ARTICLES FROM FINETUNED MODELS

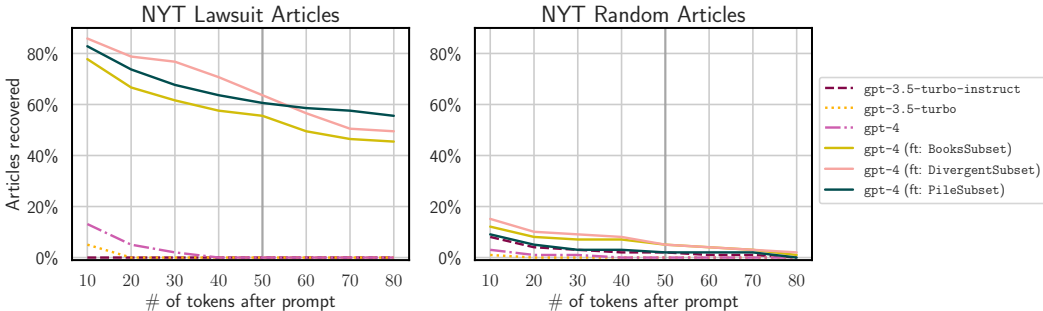

Figure 13: **Fine-tuning attack reconstructs articles from The New York Times.** We prompt models with the title and first 400 characters of NYT articles. We evaluate for how many articles we can recover the following  $N$  tokens. We do not include fine-tuned gpt-3.5-turbo models because a filter stops generations containing NYT articles.

In our experiments in Section 6.2, we find that finetuned models can reproduce targeted strings containing various types of questionable data, e.g., toxic content or copyrighted books.

Here, we consider another type of sensitive data, namely copyrighted articles from the New York Times that appear in the lawsuit filed against OpenAI and Microsoft (Grynbaum & Mac, 2023). We find that finetuned models can regurgitate many of these articles given minimal context.

We observe that `gpt-3.5-turbo` models appear to have a filter that stops the generation process after a few tokens if the model’s output belongs to an article mentioned in the lawsuit. However, this check is not present in finetuned `gpt-4` models. Figure 13 shows how often our models could reconstruct the articles when given the title and the first 400 characters. Reconstruction was less successful for randomly selected articles from the same time period as the lawsuit articles.

#### A.14 FACTORS PREDICTING MEMORIZATION

Our paper studies memorization of a number of popular language models, either proprietary or with open weights, and finds a high variance in memorization rates across models.

In this section, we thus perform two experiments to understand factors that may influence or predict a model’s memorization rate.

**Memorization increases with overtraining.** Production models such as ChatGPT need to run inference at high speeds and be served at extreme scale. To support these requirements, an emerging trend is to “over-train” models on far more data than would be “training compute optimal” (Hoffmann et al., 2022; Touvron et al., 2023b). This helps to maximize utility at a fixed inference cost. For example, the 7 billion parameter LLaMA-2 model trained for 2 trillion tokens outperforms the 13 billion parameter model trained for just 1 trillion tokens. Given that the amount of high-quality data on the web is limited, training on such a large amount of tokens requires performing many epochs over the same data (Muennighoff et al., 2023). Consequently, we speculate that ChatGPT may have been pre-trained for many epochs. Past work has shown that this can increase memorization substantially (Carlini et al., 2023a; Kandpal et al., 2022).

To further validate this, we measure memorization in models trained for multiple epochs in Figure 14. These models were trained by Muennighoff et al. (2023) on subsets of the C4 dataset of various sizes for Chinchilla-optimal token counts, so that models trained on small dataset sizes are trained for a larger number of epochs compared to models trained on larger subsets of C4. Because these models are not aligned, we use web-text prompts to measure memorization, as we did for other unaligned open models. Figure 14 shows that models trained for multiple epochs memorize larger fractions of their training sets compared to those trained for fewer epochs, corroborating prior work. Interestingly, we also find that the fraction of the dataset that is memorized is similar for different model sizes. Chinchilla-optimal token counts scale with model size, so larger models are still memorizing more, but these models appear to use a similar fraction of their capacity to memorize training data.

If our hypothesis that ChatGPT is trained for multiple epochs is correct, this may highlight a stark downside of over-training—it induces a trade-off between privacy and inference efficiency.

**Model performance does not predict memorization.** Memorization could be benign, or even helpful, for tasks which depend on knowledge recall (Kandpal et al. (2023)). Here, we thus investigate whether the effectiveness of our attacks correlates with performance evaluations reported alongside each model’s release. In Figure 15, we plot the success of our web-text prompting attack vs the piqa, hellaswag, lambada, winog, arc-e, and arc-c benchmarks, for a number of open models. Overall, we find no clear correlation between model performance and memorization (except for the possibly coincidental finding that the model with the best performance, ChatGPT, is also the model with the highest rate of memorization).

#### A.15 EVALUATION ACROSS DATASETS

Figure 16 studies the amount of memorization identified as a result of adding each of the four datasets that make up AUXDATASET. We plot both the total number of examples found in each dataset, and also the number of unique examples found only in that dataset. As expected, Dolma, the largest 5TB dataset, contains the largest number of memorized examples.

Figure 14: The fraction of a model’s dataset extracted by our attack scales with the number of epochs. These models are trained in Muennighoff et al. (2023) for Chinchilla optimal token counts.

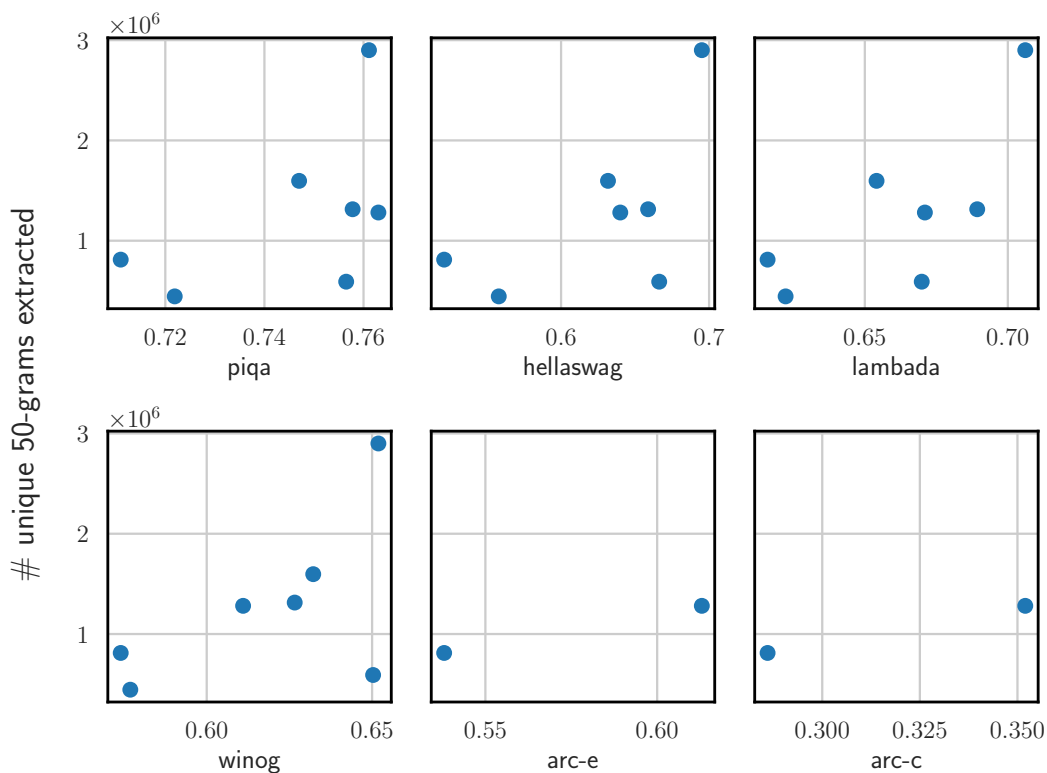

Figure 15: # unique 50-grams extracted from each model (data from Table 1) versus model performance on each of the listed benchmark tasks. There is not a strong correlation between # unique 50-grams extracted and model performance. Extraction is a different property of a model than model performance on benchmark tasks.

But we were surprised to find that scale does not completely determine the number of memorized samples identified. The 1TB RefinedWeb dataset finds the least memorization, and almost all memorization found by the 2TB RedPajama dataset was already covered by one of the other datasets. We believe that this is caused by discrepancies between the distribution of each of these datasets and the dataset on which `gpt-3.5-turbo` was trained. For example, it suggests that `gpt-3.5-turbo`’s training dataset is more similar to Dolma or The Pile than RefinedWeb—although we leave a more thorough investigation of this to future work.

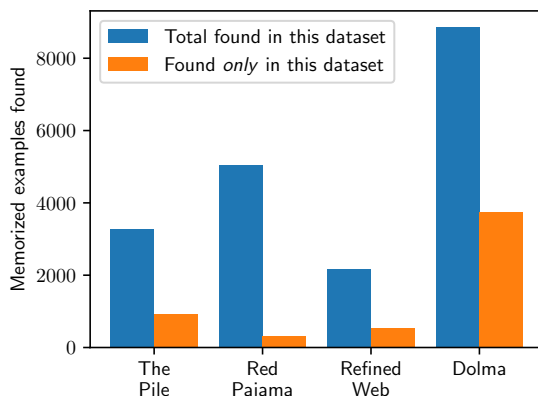

Figure 16: Number of examples recovered from each constituent of our auxiliary dataset. While there is some correlation between size and number of memorized examples identified, the 1TB RefinedWeb dataset reveals less memorized data than the 400GB Pile. And even though RedPajama identifies the second most memorized examples in total, it finds the *least* unique examples because this dataset is well covered by a combination of The Pile and Dolma.

#### A.16 AN END-TO-END HIGH-PRECISION ATTACK

Our evaluation thus far has been primarily a *measurement study* of memorization across language models, because we relied on our ability to directly query the model’s (approximate) training dataset to detect memorized model outputs. But without a reliable way to predict (a priori) whether a given model output is a training example or not, we cannot directly call this an extraction *attack*.

We now show that existing techniques from the literature are sufficient to distinguish memorized training data from other generated (non-memorized) data, with high precision. In particular, we show that the membership inference attack Shokri et al. (2017) from Carlini et al. (2021) has high precision at separating memorized training data from other hallucinated data that was not contained in the training dataset. Specifically, we score each example based on their likelihood-ratio  $\frac{\text{perplexity}_{\text{LLM}}(x)}{\text{perplexity}_{\text{zlib}}(x)}$ , where the numerator corresponds to the perplexity of the text as determined by the model that generated the text, and the denominator corresponds to the entropy of the (token-decoded) sequence under `zlib` text compression. This likelihood ratio was the most effective at predicting memorization in prior work Carlini et al. (2021), and in our evaluation we find it is highly accurate in our setting as well.

Figure 17 plots how varying the membership inference threshold affects the precision of our attack. At the lowest membership inference score threshold, the attack precision is above 30% when evaluated by a manual Internet search—or still 15% when evaluated by verbatim membership in `AUX-DATASET`. By increasing the membership inference threshold, precision remains relatively constant until 1.5 at which point it begins to significantly decay. This indicates that not only is it possible to extract training data, we can—with high precision—identify when data is memorized and when it is not. However, there is still room for future work to improve the precision of this attack further.

## B VERBATIM MEMORIZED TRAINING SEQUENCES

Below we show the 100 longest memorized training examples that we extract from ChatGPT. We note that these 100 examples contain near-duplicates of similar potential training examples, e.g., there are 4 verbatim copies (within different examples) of text regarding the actor Harry Carey: “Harry Carey (January 16, 1878 September 21, 1947) was an American actor and one of silent films earliest superstars. The Runner-Up Takes It All trope as used in popular culture. When”.

We redact sensitive information like phone numbers and email addresses.

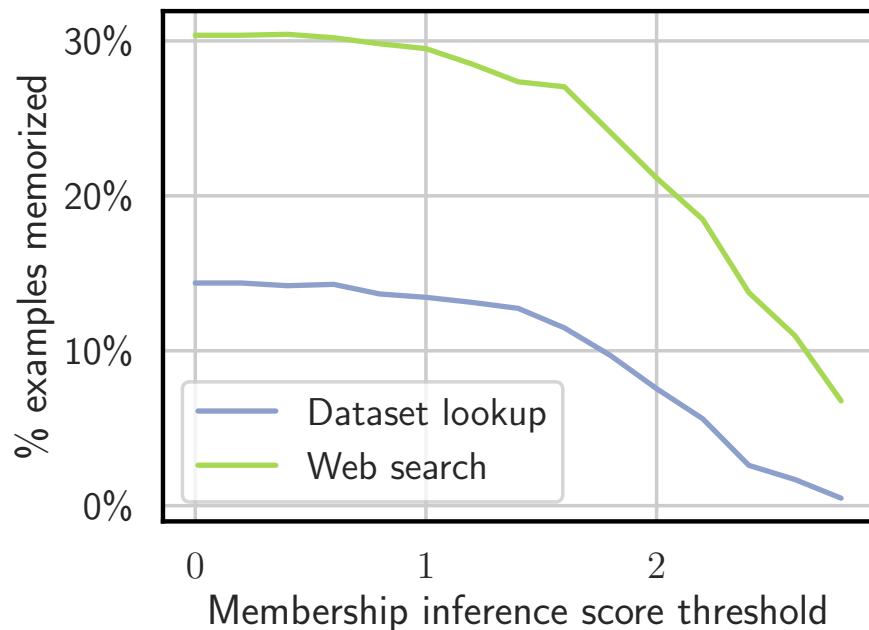

Figure 17: Out of 494 examples, the number we identify as having memorization via manual web search vs. checking whether at least 80% of the tokens are in 50-grams found in AUXDATASET. Our automatic method underestimates memorization compared to doing manual assessment using a search engine.

sources of information. Any reliance on the material on this site is at your own risk. This site may contain certain historical information. Historical information, necessarily, is not current and is provided for your reference only. We reserve the right to modify the contents of this site at any time, but we have no obligation to update any information on our site. You agree that it is your responsibility to monitor changes to our site. SECTION 4 - MODIFICATIONS TO THE SERVICE AND PRICES Prices for our products are subject to change without notice. We reserve the right at any time to modify or discontinue the Service (or any part or content thereof) without notice at any time. We shall not be liable to you or to any third-party for any modification, price change, suspension or discontinuance of the Service. SECTION 5 - PRODUCTS OR SERVICES (if applicable) Certain products or services may be available exclusively online through the website. These products or services may have limited quantities and are subject to return or exchange only according to our Return Policy. We have made every effort to display as accurately as possible the colors and images of our products that appear at the store. We cannot guarantee that your computer monitor's display of any color will be accurate. We reserve the right, but are not obligated, to limit the sales of our products or Services to any person, geographic region or jurisdiction. We may exercise this right on a case-by-case basis. We reserve the right to limit the quantities of any products or services that we offer. All descriptions of products or product pricing are subject to change at any time without notice, at the sole discretion of us. We reserve the right to discontinue any product at any time. Any offer for any product or service made on this site is void where prohibited. We do not warrant that the quality of any products, services, information, or other material purchased or obtained by you will meet your expectations, or that any errors in the Service will be corrected. SECTION 6 - ACCURACY OF BILLING AND ACCOUNT INFORMATION We reserve the right to refuse any order you place with us. We may, in our sole discretion, limit or cancel quantities purchased per person, per household or per order. These restrictions may include orders placed by or under the same customer account, the same credit card, and/or orders that use the same billing and/or shipping address. In the event that we make a change to or cancel an order, we may attempt to notify you by contacting the e-mail and/or billing address/phone number provided at the time the order was made. We reserve the right to limit or prohibit orders that, in our sole judgment, appear to be placed by dealers, resellers or distributors. You agree to provide current, complete and accurate purchase and account information for all purchases made at our store. You agree to promptly update your account and other information, including your email address and credit card numbers and expiration dates, so that we can complete your transactions and contact you as needed. SECTION 7 - OPTIONAL TOOLS We may provide you with access to third-party tools over which we neither monitor nor have any control nor input. You acknowledge and agree that we provide access to such tools "as is" and "as available" without any warranties, representations or conditions of any kind and without any endorsement. We shall have no liability whatsoever arising from or relating to your use of optional third-party tools. Any use by you of optional tools offered through the site is entirely at your own risk and discretion and you should ensure that you are familiar with and approve of the terms on which tools are provided by the relevant third-party provider(s). We may also, in the future, offer new services and/or features through the website (including, the release of new tools and resources). Such new features and/or services shall also be subject to these Terms of

on vacation in Las Vegas, my upper back, shoulders, and neck were starting to get tired/tight from me lugging around my camera gear (DSLR camera, battery grip/pack, & speedlight flash) around my neck for 4 days at roughly 4 hours each day. My legs and feet were also tired from all the walking, standing, and running on the Strip. I was looking for a massage and the place that I was staying at offered massages but I found the prices to be too expensive. I had also tried the water massage beds offered in some malls (including the Showcase Mall) and although those water massage beds were relaxing, I preferred a more firm, deep tissue type massage to try to get rid of the knots that I was sure were building up in my shoulders & upper back. As luck would have it, there was a discussion forum about firm, deep tissue massages in the Las Vegas Talk forum. I checked out the prices and the review and called to make an appointment. Even factoring the Lyft ride to/from the place, I calculated the price to be less than how much it would cost me to get a similar type massage at the place I was staying at or any Strip hotel spa. I arrived early and was told that I should come back in ~30 minutes. Since the temperature was cold outside, I asked if I could stay inside and there wasn't an issue. I was told that I could lay on the bed while I waited but I decided I would just sit there. I used the Yelp app on my phone to check in and there was a discount. I spoke with the person behind the counter about the discount and I was informed that because I wanted a 90 minute massage and the 90 minute massage was already discounted, it would not apply. When the person was ready I was escorted to the room. Inside the room there were 2 massage beds. I was asked how long I wanted and I mentioned that I wanted 90 minutes. I was then asked to undress and go underneath the towel. I was told that this place also specializes in back walking so I requested a few minutes of that. Above the massage tables are 2 bars so the massage therapist can hold on as to not apply all her weight on the customer. I thought that I could handle firm massages but Kim gave me one of the firmest, deep tissue massages that I've ever experienced. The oil that she used had a burning and soothing feeling to it. Part of the 90 minute massage also involved stretching certain muscles. At the end of the 90 minutes, even though I was a little bit sore from the deep tissue massage, I felt a lot better. When the massage was over, I got dressed, went to the front counter, and paid as well as left a tip. While I used the Lyft app on my phone to get ride to get back to the Strip, I was offered a loyalty card. The only thing about the loyalty card is that it was created/made for 60 minute massages and not 90 minute massages since a 90 minute massage only gets 1 stamp on the card. If you like firm (deep tissue) massages, this is the place to go

Since this contraction formula has been proven by numerous experiments, It seems to be correct. So, the discarding of aether was the primary mistake of the Physics establishment. Empty space is not empty. It has physical properties, an Impedance, Free Power constant of electrical permittivity, and Free Power constant of magnetic permeability. Truly empty space would have no such properties! The Aether is seething with energy. Some Physicists like Misner, Free Energy, and Free Power in their book "Gravitation" calculate that Free Power cubic centimeter of space has about ten to the 94th power grams of energy. Using the formula  $E=mc^2$  Free Electricity that comes to Free Power tremendous amount of energy. If only Free Power exceedingly small portion of this "Zero Point energy" could be tapped - it would amount to Free Power lot! Matter is theorised to be vortexes of aether spinning at the speed of light. that is why electron positron pair production can occur in empty space if Free Power sufficiently electric field is imposed on that space. It that respect matter can be created. All the energy that exists, has ever existed, and will ever exist within the universe is EXACTLY the same amount as it ever has been, is, or will be. You can't create more energy. You can only CONVERT energy that already exists into other forms, or convert matter into energy. And there is ALWAYS loss. Always. There is no way around this simple truth of the universe, sorry. There is Free Power serious problem with your argument. "Free Power me one miracle and we will explain the rest." Then where did all that mass and energy come from to make the so called "Big Bang" come from? Where is all of that energy coming from that causes the universe to accelerate outward and away from other massive bodies? Therein lies the real magic doesn't it? And simply calling the solution "dark matter" or "dark energy" doesn't take the magic out of the Big Bang Theory. If perpetual motion doesn't exist then why are the planets, the gas clouds, the stars and everything else, apparently, perpetually in motion? What was called religion yesterday is called science today. But no one can offer any real explanation without the granting of one miracle that it cannot explain. Chink, chink goes the armor. You asked about the planets as if they are such machines. But they aren't. Free Power they spin and orbit for Free Power very long time? Yes. Forever? Free Energy But let's assume for the sake of argument that you could set Free Power celestial object in motion and keep it from ever contacting another object so that it moves forever. (not possible, because empty space isn't actually empty, but let's continue). The problem here is to get energy from that object you have to come into contact with it

There was a man who had two sons. The younger one said to his father, 'Father, give me my share of the estate.' So he divided his property between them. "Not long after that, the younger son got together all he had, set off for a distant country and there squandered his wealth in wild living. After he had spent everything, there was a severe famine in that whole country, and he began to be in need. So he went and hired himself out to a citizen of that country, who sent him to his fields to feed pigs. He longed to fill his stomach with the pods that the pigs were eating, but no one gave him anything. "When he came to his senses, he said, 'How many of my father's hired servants have food to spare, and here I am starving to death! I will set out and go back to my father and say to him: Father, I have sinned against heaven and against you. I am no longer worthy to be called your son; make me like one of your hired servants.' So he got up and went to his father. "But while he was still a long way off, his father saw him and was filled with compassion for him; he ran to his son, threw his arms around him and kissed him. "The son said to him, 'Father, I have sinned against heaven and against you. I am no longer worthy to be called your son.' "But the father said to his servants, 'Quick! Bring the best robe and put it on him. Put a ring on his finger and sandals on his feet. Bring the fattened calf and kill it. Let's have a feast and celebrate. For this son of mine was dead and is alive again; he was lost and is found.' So they began to celebrate. "Meanwhile, the older son was in the field. When he came near the house, he heard music and dancing. So he called one of the servants and asked him what was going on. 'Your brother has come,' he replied, 'and your father has killed the fattened calf because he has him back safe and sound.' "The older brother became angry and refused to go in. So his father went out and pleaded with him. But he answered his father, 'Look! All these years I've been slaving for you and never disobeyed your orders. Yet you never gave me even a young goat so I could celebrate with my friends. But when this son of yours who has squandered your property with prostitutes comes home, you kill the fattened calf for him!'"

The Lord said to Samuel, "How long will you grieve over Saul? I have rejected him from being king over Israel. Fill your horn with oil and set out; I will send you to Jesse the Bethlehemite, for I have provided for myself a king among his sons." 2 Samuel said, "How can I go? If Saul hears of it, he will kill me." And the Lord said, "Take a heifer with you, and say, 'I have come to sacrifice to the Lord.' 3 Invite Jesse to the sacrifice, and I will show you what you shall do; and you shall anoint for me the one whom I name to you." 4 Samuel did what the Lord commanded, and came to Bethlehem. The elders of the city came to meet him trembling, and said, "Do you come peaceably?" 5 He said, "Peaceably; I have come to sacrifice to the Lord; sanctify yourselves and come with me to the sacrifice." And he sanctified Jesse and his sons and invited them to the sacrifice. 6 When they came, he looked on Eliab and thought, "Surely the Lord's anointed is now before the Lord." 7 But the Lord said to Samuel, "Do not look on his appearance or on the height of his stature, because I have rejected him; for the Lord does not see as mortals see; they look on the outward appearance, but the Lord looks on the heart." 8 Then Jesse called Abinadab, and made him pass before Samuel. He said, "Neither has the Lord chosen this one." 9 Then Jesse made Shammah pass by. And he said, "Neither has the Lord chosen this one." 10 Jesse made seven of his sons pass before Samuel, and Samuel said to Jesse, "The Lord has not chosen any of these." 11 Samuel said to Jesse, "Are all your sons here?" And he said, "There remains yet the youngest, but he is keeping the sheep." And Samuel said to Jesse, "Send and bring him; for we will not sit down until he comes here." 12 He sent and brought him in. Now he was ruddy, and had beautiful eyes, and was handsome. The Lord said, "Rise and anoint him; for this is the one." 13 Then Samuel took the horn of oil, and anointed him in the presence of his brothers; and the spirit of the Lord came mightily upon David from that day forward. Samuel then set out and went to Ramah

. Bluegreens The Cliffs at Long Creek resort in Ridgedale, Missouri offers five bedroom patio homes and two bedroom lodge villas for your next vacation. Find Maps, Photos, Videos and Area Information. the LORD was about to take Elijah up to heaven by a whirlwind, Elijah and Elisha were on their way from Gilgal. Elijah said to Elisha, "Stay here; for the LORD has sent me as far as Bethel." But Elisha said, "As the LORD lives, and as you yourself live, I will not leave you." So they went down to Bethel. Then Elijah said to him, "Stay here; for the LORD has sent me to the Jordan." But he said, "As the LORD lives, and as you yourself live, I will not leave you." So the two of them went on. Fifty men of the company of prophets also went, and stood at some distance from them, as they both were standing by the Jordan. Then Elijah took his mantle and rolled it up, and struck the water; the water was parted to the one side and to the other, until the two of them crossed on dry ground. When they had crossed, Elijah said to Elisha, "Tell me what I may do for you, before I am taken from you." Elisha said, "Please let me inherit a double share of your spirit." He responded, "You have asked a hard thing; yet, if you see me as I am being taken from you, it will be granted you; if not, it will not." As they continued walking and talking, a chariot of fire and horses of fire separated the two of them, and Elijah ascended in a whirlwind into heaven. Elisha kept watching and crying out, "Father, father! The chariots of Israel and its horsemen!" But when he could no longer see him, he grasped his own clothes and tore them in two pieces. He picked up the mantle of Elijah that had fallen from him, and went back and stood on the bank of the Jordan. He took the mantle of Elijah that had fallen from him, and struck the water, saying, "Where is the LORD, the God of Elijah?" When he had struck the water, the water was parted to the one side and to the other, and Elisha went over

houses, and this house lie waste? Now therefore thus saith the LORD of hosts; Consider your ways. Ye have sown much, and bring in little; ye eat, but ye have not enough; ye drink, but ye are not filled with drink; ye clothe you, but there is none warm; and he that earneth wages earneth wages to put it into a bag with holes. Thus saith the LORD of hosts; Consider your ways. Go up to the mountain, and bring wood, and build the house; and I will take pleasure in it, and I will be glorified, saith the LORD. Ye looked for much, and, lo, it came to little; and when ye brought it home, I did blow upon it. Why? saith the LORD of hosts. Because of mine house that is waste, and ye run every man unto his own house. Therefore the heaven over you is stayed from dew, and the earth is stayed from her fruit. And I called for a drought upon the land, and upon the mountains, and upon the corn, and upon the new wine, and upon the oil, and upon that which the ground bringeth forth, and upon men, and upon cattle, and upon all the labour of the hands. Then Zerubbabel the son of Shealtiel, and Joshua the son of Josedech, the high priest, with all the remnant of the people, obeyed the voice of the LORD their God, and the words of Haggai the prophet, as the LORD their God had sent him, and the people did fear before the LORD. Then spake Haggai the LORD's messenger in the LORD's message unto the people, saying, I am with you, saith the LORD. And the LORD stirred up the spirit of Zerubbabel the son of Shealtiel, governor of Judah, and the spirit of Joshua the son of Josedech, the high priest, and the spirit of all the remnant of the people; and they came and did work in the house of the LORD of hosts, their God, in the four and twentieth day of the sixth month, in the second year of Darius the king

Full Text Available An increasing number of studies indicate that dairy products, including whey protein, alleviate several disorders of the metabolic syndrome. Here, we investigated the effects of whey protein isolate (whey in mice fed a high-fat diet hypothesising that the metabolic effects of whey would be associated with changes in the gut microbiota composition. Five-week-old male C57BL/6 mice were fed a high-fat diet ad libitum for 14 weeks with the protein source being either whey or casein. Faeces were collected at week 0, 7, and 13 and the fecal microbiota was analysed by denaturing gradient gel electrophoresis analyses of PCR-derived 16S rRNA gene (V3-region amplicons. At the end of the study, plasma samples were collected and assayed for glucose, insulin and lipids. Whey significantly reduced body weight gain during the first four weeks of the study compared with casein ( $P < 0.001$ - $0.05$ ). Hereafter weight gain was similar resulting in a 15% lower final body weight in the whey group relative to casein ( $34.0A \pm 1.0$  g vs.  $40.2A \pm 1.3$  g,  $P < 0.001$ ). Food intake was unaffected by protein source throughout the study period. Fasting insulin was lower in the whey group ( $P < 0.01$ ) and glucose clearance was improved after an oral glucose challenge ( $P < 0.05$ ). Plasma cholesterol was lowered by whey compared to casein ( $P < 0.001$ ). The composition of the fecal microbiota differed between high- and low-fat groups at 13 weeks ( $P < 0.05$ ) whereas no difference was seen between whey and casein. In conclusion, whey initially reduced weight gain in young C57BL/6 mice fed a high-fat diet compared to casein. Although the effect on weight gain ceased, whey alleviated glucose intolerance, improved insulin sensitivity and reduced plasma cholesterol. These findings could not be explained by changes in food intake or gut microbiota composition. Further studies are needed to clarify the mechanisms behind the metabolic effects of whey

The book of the generation of Jesus Christ, the son of David, the son of Abraham. Abraham begat Isaac; and Isaac begat Jacob; and Jacob begat Judas and his brethren; And Judas begat Phares and Zara of Thamar; and Phares begat Esrom; and Esrom begat Aram; And Aram begat Aminadab; and Aminadab begat Naasson; and Naasson begat Salmon; And Salmon begat Booz of Rachab; and Booz begat Obed of Ruth; and Obed begat Jesse; And Jesse begat David the king; and David the king begat Solomon of her that had been the wife of Urias; And Solomon begat Roboam; and Roboam begat Abia; and Abia begat Asa; And Asa begat Josaphat; and Josaphat begat Joram; and Joram begat Ozias; And Ozias begat Joatham; and Joatham begat Achaz; and Achaz begat Ezekias; And Ezekias begat Manasses; and Manasses begat Amon; and Amon begat Josias; And Josias begat Jechonias and his brethren, about the time they were carried away to Babylon: And after they were brought to Babylon, Jechonias begat Salathiel; and Salathiel begat Zorobabel; And Zorobabel begat Abiud; and Abiud begat Eliakim; and Eliakim begat Azor; And Azor begat Sadoc; and Sadoc begat Achim; and Achim begat Eliud; And Eliud begat Eleazar; and Eleazar begat Matthan; and Matthan begat Jacob; And Jacob begat Joseph the husband of Mary, of whom was born Jesus, who is called Christ. So all the generations from Abraham to David are fourteen generations; and from David until the carrying away into Babylon are fourteen generations; and from the carrying away into Babylon unto Christ are fourteen generations

From the celebrated author of *The Secret Life of Bees*, a #1 New York Times bestselling novel about two unforgettable American women. Writing at the height of her narrative and imaginative gifts, Sue Monk Kidd presents a masterpiece of hope, daring, the quest for freedom, and the desire to have a voice in the world. Hetty "Handful" Grimke, an urban slave in early nineteenth century Charleston, yearns for life beyond the suffocating walls that enclose her within the wealthy Grimke household. The Grimke's daughter, Sarah, has known from an early age she is meant to do something large in the world, but she is hemmed in by the limits imposed on women. Kidd's sweeping novel is set in motion on Sarah's eleventh birthday, when she is given ownership of ten year old Handful, who is to be her handmaid. We follow their remarkable journeys over the next thirty five years, as both strive for a life of their own, dramatically shaping each other's destinies and forming a complex relationship marked by guilt, defiance, estrangement and the uneasy ways of love. As the stories build to a riveting climax, Handful will endure loss and sorrow, finding courage and a sense of self in the process. Sarah will experience crushed hopes, betrayal, unrequited love, and ostracism before leaving Charleston to find her place alongside her fearless younger sister, Angelina, as one of the early pioneers in the abolition and women's rights movements. Inspired by the historical figure of Sarah Grimke, Kidd goes beyond the record to flesh out the rich interior lives of all of her characters, both real and invented, including Handful's cunning mother, Charlotte, who courts danger in her search for something better. This exquisitely written novel is a triumph of storytelling that looks with unswerving eyes at a devastating wound in American history, through women whose struggles for liberation, empowerment, and expression will leave no reader unmoved. From the Trade Paperback edition

The best time to take sildenafil is about 1 hour before sexual activity, but you can take the medication any time from 4 hours to 30 minutes before sexual activity. Sildenafil usually should not be taken more than once every 24 hours. If you have certain health conditions or are taking certain medications, your doctor may tell you to take sildenafil less often. You can take sildenafil with or without food. However, if you take sildenafil with a high-fat meal, it will take longer for the medication to start to work. If you are taking sildenafil to treat PAH, follow your doctor's directions and the guidelines in this paragraph. You will probably take sildenafil three times a day with or without food. Take sildenafil at around the same times every day, and space your doses about 4 to 6 hours apart. Follow the directions on your prescription label carefully, and ask your doctor or pharmacist to explain any part you do not understand. Take sildenafil exactly as directed. Do not take more or less of it or take it more often than prescribed by your doctor. Shake the liquid well for 10 seconds before each use to mix the medication evenly. Use the oral syringe provided with your medication to measure and take your dose. Follow the manufacturer's directions to use and clean the oral syringe. Do not mix the liquid with other medications or add anything to flavor the medication. If you are taking sildenafil for erectile dysfunction, your doctor will probably start you on an average dose of sildenafil and increase or decrease your dose depending on your response to the medication. Tell your doctor if sildenafil is not working well or if you are experiencing side effects. If you are taking sildenafil for PAH, you should know that sildenafil controls PAH but does not cure it. Continue to take sildenafil even if you feel well. Do not stop taking sildenafil without talking to your doctor. Ask your pharmacist or doctor for a copy of the manufacturer's information for the patient

with a timely novel that interweaves past and present to explore the human capacity for resiliency and compassion in times of great upheaval. How could two hardworking people do everything right in life, a woman asks, and end up destitute? Willa Knox and her husband followed all the rules as responsible parents and professionals, and have nothing to show for it but debts and an inherited brick house that is falling apart. The magazine where Willa worked has folded; the college where her husband had tenure has closed. Their dubious shelter is also the only option for a disabled father-in-law and an exasperating, free-spirited daughter. When the family's one success story, an Ivy-educated son, is uprooted by tragedy he seems likely to join them, with dark complications of his own. In another time, a troubled husband and public servant asks, How can a man tell the truth, and be reviled for it? A science teacher with a passion for honest investigation, Thatcher Greenwood finds himself under siege: his employer forbids him to speak of the exciting work just published by Charles Darwin. His young bride and social-climbing mother-in-law bristle at the risk of scandal, and dismiss his worries that their elegant house is unsound. In a village ostensibly founded as a benevolent Utopia, Thatcher wants only to honor his duties, but his friendships with a woman scientist and a renegade newspaper editor threaten to draw him into a vendetta with the town's powerful men. Unsheltered is the compulsively readable story of two families, in two centuries, who live at the corner of Sixth and Plum in Vineland, New Jersey, navigating what seems to be the end of the world as they know it. With history as their tantalizing canvas, these characters paint a startlingly relevant portrait of life in precarious times when the foundations of the past have failed to prepare us for the future.

In American English, quot;phonographquot;, properly specific to machines made by Edison, was sometimes used in a generic sense as early as the 1890s to include cylinder-playing machines made by others

Full Text Available Abstract Background Histone deacetylase inhibitors (HDACi induce hyperacetylation of core histones modulating chromatin structure and affecting gene expression. These compounds are also able to induce growth arrest, cell differentiation, and apoptotic cell death of tumor cells in vitro as well as in vivo. Even though several genes modulated by HDAC inhibition have been identified, those genes clearly responsible for the biological effects of these drugs have remained elusive. We investigated the pharmacological effect of the HDACi and potential anti-cancer agent Trichostatin A (TSA) on primary T cells. Methods To ascertain the effect of TSA on resting and activated T cells we used a model system where an enriched cell population consisting of primary T-cells was stimulated in vitro with immobilized anti-CD3/anti-CD28 antibodies whilst exposed to pharmacological concentrations of Trichostatin A. Results We found that this drug causes a rapid decline in cytokine expression, accumulation of cells in the G1 phase of the cell cycle, and induces apoptotic cell death. The mitochondrial respiratory chain (MRC) plays a critical role in the apoptotic response to TSA, as dissipation of mitochondrial membrane potential and reactive oxygen species (ROS) scavengers block TSA-induced T-cell death. Treatment of T cells with TSA results in the altered expression of a subset of genes involved in T cell responses, as assessed by microarray gene expression profiling. We also observed up- as well as down-regulation of various costimulatory/adhesion molecules, such as CD28 and CD154, important for T-cell function. Conclusions Taken together, our findings indicate that HDAC inhibitors have an immunomodulatory potential that may contribute to the potency and specificity of these antineoplastic compounds and might be useful in the treatment of autoimmune disorders

In those strange old times, when fantastic dreams and madmen's reveries were realized among the actual circumstances of life, two persons met together at an appointed hour and place. One was a lady, graceful in form and fair of feature, though pale and troubled, and smitten with an untimely blight in what should have been the fullest bloom of her years; the other was an ancient and meanly-dressed woman, of ill-favored aspect, and so withered, shrunken, and decrepit, that even the space since she began to decay must have exceeded the ordinary term of human existence. In the spot where they encountered, no mortal could observe them. Three little hills stood near each other, and down in the midst of them sunk a hollow basin, almost mathematically circular, two or three hundred feet in breadth, and of such depth that a stately cedar might but just be visible above the sides. Dwarf pines were numerous upon the hills, and partly fringed the outer verge of the intermediate hollow, within which there was nothing but the brown grass of October, and here and there a tree trunk that had fallen long ago, and lay mouldering with no green successor from its roots. One of these masses of decaying wood, formerly a majestic oak, rested close beside a pool of green and sluggish water at the bottom of the basin. Such scenes as this (so gray tradition tells) were once the resort of the Power of Evil and his plighted subjects; and here, at midnight or on the dim verge of evening, they were said to stand round the mantling pool, disturbing its putrid waters in the performance of an impious baptismal rite. The chill beauty of an autumnal sunset was now gilding the three hill-tops, whence a paler tint stole down their sides into the hollow

-work system similar to Adam Back's Hashcash [6], rather than newspaper or Usenet posts. The proof-of-work involves scanning for a value that when hashed, such as with SHA-256, the hash begins with a number of zero bits. The average work required is exponential in the number of zero bits required and can be verified by executing a single hash. For our timestamp network, we implement the proof-of-work by incrementing a nonce in the block until a value is found that gives the block's hash the required zero bits. Once the CPU effort has been expended to make it satisfy the proof-of-work, the block cannot be changed without redoing the work. As later blocks are chained after it, the work to change the block would include redoing all the blocks after it. The proof-of-work also solves the problem of determining representation in majority decision making. If the majority were based on one-IP-address-one-vote, it could be subverted by anyone able to allocate many IPs. Proof-of-work is essentially one-CPU-one-vote. The majority decision is represented by the longest chain, which has the greatest proof-of-work effort invested in it. If a majority of CPU power is controlled by honest nodes, the honest chain will grow the fastest and outpace any competing chains. To modify a past block, an attacker would have to redo the proof-of-work of the block and all blocks after it and then catch up with and surpass the work of the honest nodes. We will show later that the probability of a slower attacker catching up diminishes exponentially as subsequent blocks are added. To compensate for increasing hardware speed and varying interest in running nodes over time, the proof-of-work difficulty is determined by a moving average targeting an average number of blocks per hour. If they're generated too fast, the difficulty increases.

. Tata Motors has auto manufacturing and assembly plants in Jamshedpur, Pantnagar, Lucknow, Sanand, Dharwad, and Pune in India, as well as in Argentina, South Africa, Great Britain and Thailand. It has research and development centres in Pune, Jamshedpur, Lucknow, and Dharwad, India and in South Korea, Great Britain and Spain. Tata Motors' principal subsidiaries purchased the English premium car maker Jaguar Land Rover (the maker of Jaguar and Land Rover cars) and the South Korean commercial vehicle manufacturer Tata Daewoo. Tata Motors has a bus-manufacturing joint venture with Marcopolo S.A. (Tata Marcopolo), a construction-equipment manufacturing joint venture with Hitachi (Tata Hitachi Construction Machinery), and a joint venture with Fiat Chrysler which manufactures automotive components and Fiat Chrysler and Tata branded vehicles. Founded in 1945 as a manufacturer of locomotives, the company manufactured its first commercial vehicle in 1954 in a collaboration with Daimler-Benz AG, which ended in 1969. Tata Motors entered the passenger vehicle market in 1991 with the launch of the Tata Sierra, becoming the first Indian manufacturer to achieve the capability of developing a competitive indigenous automobile. In 1998, Tata launched the first fully indigenous Indian passenger car, the Indica, and in 2008 launched the Tata Nano, the world's cheapest car. Tata Motors acquired the South Korean truck manufacturer Daewoo Commercial Vehicles Company in 2004 and purchased Jaguar Land Rover from Ford in 2008. Tata Motors is listed on the (BSE) Bombay Stock Exchange, where it is a constituent of the BSE SENSEX index, the National Stock Exchange of India, and the New York Stock

If any of these terms are deemed invalid or unenforceable for any reason (including, but not limited to the exclusions and limitations set out above), then the invalid or unenforceable provision will be severed from these terms and the remaining terms will continue to apply. Failure of the Company to enforce any of the provisions set out in these Terms and Conditions and any Agreement, or failure to exercise any option to terminate, shall not be construed as waiver of such provisions and shall not affect the validity of these Terms and Conditions or of any Agreement or any part thereof, or the right thereafter to enforce each and every provision. These Terms and Conditions shall not be amended, modified, varied or supplemented except in writing and signed by duly authorised representatives of the Company. Notification of Changes The Company reserves the right to change these conditions from time to time as it sees fit and your continued use of the site will signify your acceptance of any adjustment to these terms. If there are any changes to our privacy policy, we will announce that these changes have been made on our home page and on other key pages on our site. If there are any changes in how we use our site customers' Personally Identifiable Information, notification by e-mail or postal mail will be made to those affected by this change. Any changes to our privacy policy will be posted on our web site 30 days prior to these changes taking place. You are therefore advised to re-read this statement on a regular basis. These terms and conditions form part of the Agreement between the Client and ourselves. Your accessing of this website and/or undertaking of a booking or Agreement indicates your understanding, agreement to and acceptance, of the Disclaimer Notice and the full Terms and Conditions contained herein. Your statutory Consumer Rights are unaffected.

. SECTION 8 - THIRD-PARTY LINKS Certain content, products and services available via our Service may include materials from third-parties. Third-party links on this site may direct you to third-party websites that are not affiliated with us. We are not responsible for examining or evaluating the content or accuracy and we do not warrant and will not have any liability or responsibility for any third-party materials or websites, or for any other materials, products, or services of third-parties. We are not liable for any harm or damages related to the purchase or use of goods, services, resources, content, or any other transactions made in connection with any third-party websites. Please review carefully the third-party's policies and practices and make sure you understand them before you engage in any transaction. Complaints, claims, concerns, or questions regarding third-party products should be directed to the third-party. SECTION 9 - USER COMMENTS, FEEDBACK AND OTHER SUBMISSIONS If, at our request, you send certain specific submissions (for example contest entries) or without a request from us you send creative ideas, suggestions, proposals, plans, or other materials, whether online, by email, by postal mail, or otherwise (collectively, 'comments'), you agree that we may, at any time, without restriction, edit, copy, publish, distribute, translate and otherwise use in any medium any comments that you forward to us. We are and shall be under no obligation (1) to maintain any comments in confidence; (2) to pay compensation for any comments; or (3) to respond to any comments. We may, but have no obligation to, monitor, edit or remove content that we determine in our sole discretion are unlawful, offensive, threatening, libelous, defamatory, pornographic, obscene or otherwise objectionable or violates any party's intellectual property or these Terms of
