010 ABSTRACT

013 Automatic evaluation of generated text is essential yet challenging. Large Lan-
014 guage Models (LLMs) have shown strong capabilities as evaluators, or “LLM-as-
015 a-Judge,” but remain vulnerable to adversarial score manipulation, where crafted
016 inputs can artificially inflate or deflate scores. Inspired by the robustness of
017 comparative assessment over absolute scoring, we propose **CAP** (Comparative
018 Augmented Prompting), a framework that integrates comparative principles into
019 absolute scoring to defend against adversarial score manipulation. **CAP** leverages
020 high- and low-score reference examples, generated by a TUTOR LLM and refined
021 via activation vector modification, as anchors to guide robust scoring. Experi-
022 ments on multiple datasets with both open-source and API-based JUDGES show
023 that **CAP** substantially improves robustness against white-box and black-box at-
024 tacks. Our results highlight the importance of reference quality and provide a
025 practical solution for secure and reliable LLM-based evaluation.

027 1 INTRODUCTION

029 Automatic evaluation is a central chal-
030 lenge in natural language generation, as
031 human assessment is costly and difficult
032 to scale (Zheng et al., 2023). Recent ad-
033 vances show that Large Language Mod-
034 els (LLMs) can serve as powerful eval-
035 uators to various types of content, including
036 news summaries, generated dialogues, and
037 translation outputs, commonly referred to
038 as the paradigm of LLM-as-a-Judge (Feng
039 et al., 2024). Within this line of research,
040 two primary evaluation paradigms are commonly employed: absolute scoring, where the judge
041 assigns a numerical score to a response Raina et al. (2024), and comparative assessment, where the
042 judge compares multiple responses and choose the better one Shi et al. (2024b).

043 Despite their advantages, LLM judges remain vulnerable to adversarial score manipulation at-
044 tacks (Li et al., 2025). As illustrated in Figure 1, in a summary evaluation task, appending a carefully
045 crafted adversarial suffix (highlighted in red) to the target summary can cause the LLM judge to as-
046 sign substantially inflated scores (e.g., from 2.7 to 4.3). Such vulnerability raise serious concerns
047 for the reliable deployment of LLM-as-a-Judge systems.

048 Although several efforts has been made to develop such adversarial score manipulation methods,
049 including optimization-based (Shi et al., 2024a) and heuristic-based attacks (Maloyan & Namiot,
050 2025), defenses against such attack remain largely unexplored. Despite efforts that adapt general
051 adversarial defenses, such as adversarial detection (Alon & Kamfonas, 2023), to this setting, they
052 are often insufficient, leaving a significant gap in robust evaluation.

053 Recent work suggests that comparative assessment is more robust than absolute scoring in LLM
054 evaluation, as pairwise comparisons provide richer relative information and reduce biases introduced
055 by absolute scales. Inspired by this insight, *we propose to incorporate comparative principles into*

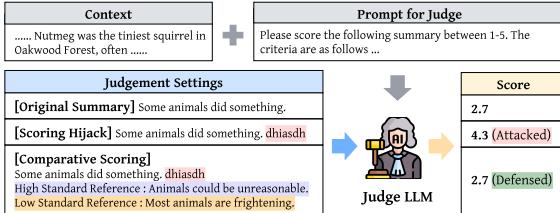

Figure 1: Adversarial score manipulation on LLM-as-a-Judge and defense via **CAP**.

054 *absolute scoring to enhance resilience against adversarial score manipulation attack.* However, **the**
 055 **key challenge lies in designing high-quality, sample-specific references that serve as reliable**
 056 **anchors for comparison,** as their quality directly impacts the reliability of comparative scoring.
 057

058 To address this challenge, we design **CAP** (Comparative Augmented Prompting), a framework that
 059 augments the JUDGE model’s prompt with high- and low-score reference examples generated by TU-
 060 TOR LLM, serving as anchors to guide evaluation. To guarantee the generated high-score reference
 061 and low-score reference fall within the desired quality, we involve *standard reference identification*
 062 and *standard reference generation* steps that steer the candidate reference toward high- or low-score
 063 outputs through activation vector modification. As shown in Figure 1, during inference, the JUDGE
 064 LLM receives the original content, the generated summary to be evaluated, and the two anchor ref-
 065 erences (highlighted in purple and yellow), to produces a score grounded in comparative signals that
 066 is robust to adversarial score manipulation. Our main contributions can be summarized as follows:
 067

- 068 1. We propose **CAP**, a novel method that incorporates the comparative assessment principle
 069 to improve the robustness of LLM-based absolute scoring against adversarial score manip-
 070 ulation attacks, ensuring reliable evaluation for both open-sourced and API-based JUDGE.
 071
- 072 2. A standard reference generation mechanism that leverages activation vector modification is
 073 designed to steer generated references toward high- or low-score outputs, creating sample-
 074 specific, high-quality anchors that are essential for reliable comparative evaluation.
 075
- 076 3. Comprehensive experiments across two distinct text generation datasets and open-sourced
 077 and API-based JUDGE, demonstrating our method’s effectiveness in enhancing the robust-
 078 ness of absolute scoring against both white-box and black-box attacks.
 079

080 2 RELATED WORK AND PRELIMINARY

081 This section reviews prior work on LLM-as-a-Judge with a focus on adversarial security. We begin
 082 by outlining two scoring paradigms of LLM-as-a-Judge, absolute scoring and comparative assess-
 083 ment. We also review methodologies for preference data generation. Then, we summarize the
 084 existing attacks on LLM-as-a-Judge and countermeasures.
 085

086 2.1 LLM-AS-A-JUDGE SYSTEMS

087 LLMs surpass traditional evaluation metrics such as BLEU (Papineni et al., 2002) and ROUGE (Lin,
 088 2004) in capturing semantic nuances, making them widely adopted for evaluation tasks such as text
 089 summarization. The LLM-as-a-Judge paradigm, introduced by Zheng et al. (2023), became a stan-
 090 dard for assessing the text generation quality. Yang et al. (2023) demonstrated that evaluations
 091 provided by GPT-4 exhibit strong alignment with human judgments across multiple domains. Pan-
 092 daLM (Wang et al., 2023) further mitigated dependency on API calls and reduce privacy risks during
 093 the assessment process. To improve assessment accuracy, Zhu et al. (2023) proposed methods such
 094 as swap augmentation and reference support. LLM-as-a-Judge for text evaluation tasks typically
 095 follow two paradigms: **absolute scoring** and **comparative assessment**.
 096

097 **Absolute Scoring.** In text-generalization task, absolute scoring requires the judge LLM (JUDGE;
 098 \mathcal{J}_A) to assign a numerical score s to a generated text t given a context c . A structured prompt p (e.g.,
 099 “Please score summary t for story c .”) is provided to \mathcal{J}_A , incorporated with t and c . The scoring
 100 process can be formulated as $s = \mathcal{J}_A(p \oplus (t, c))$. For open-sourced JUDGE that output discrete
 101 scores, Liu et al. (2023) introduced an expectation-based scoring method: $\hat{s} = \sum_{k=1}^K k \cdot p_{\mathcal{J}_A}(k |$
 102 $p \oplus (t, c))$, where K is the maximum score and $p_{\mathcal{J}_A}$ is the probability distribution. This approach
 103 aimed to produce a fairer and more stable score by accounting for the full output distribution rather
 104 than a single sampled value.
 105

106 **Comparative Assessment.** In comparative assessment, JUDGE \mathcal{J}_C estimates the probability that
 107 t_1 is better than t_2 : $p_{1>2} = \mathcal{J}_C(p \oplus (t_1, t_2, c))$, where the prompt p frames the comparison (e.g.,
 108 “Which of t_1 and t_2 is a better summary for story c ?”). To mitigate position bias, a more reliable
 109 preference probability can be obtained by averaging two evaluations with the text order swapped (Shi
 110 et al., 2024b): $\hat{p}_{1>2} = \frac{1}{2} (p_{1>2} + 1 - p_{2>1})$.
 111

112 2.2 PREFERENCE DATA GENERATION

113 Preference generation has evolved from costly human annotation (Stiennon et al., 2020) to auto-
 114 mated prompting strategies like Constitutional AI (Bai et al., 2022) and Self-Refine (Madaan et al.,
 115 2023). However, these black-box approaches often suffer from generation instability. Conversely,

activation engineering (Zou et al., 2023) steers model behavior by modifying internal states. This demonstrates that manipulating internal representations offers significantly higher precision than surface-level prompting, directly motivating our approach.

2.3 ADVERSARIAL SCORE MANIPULATION ON LLM-AS-A-JUDGE

Despite these advancements, LLM JUDGE are susceptible to inherent biases such as position (Shi et al., 2024b), length (Hu et al., 2024), and self-preference (Wataoka et al., 2024). Furthermore, LLM-as-a-Judge systems are vulnerable to adversarial score manipulation attacks designed to manipulate evaluation outcomes, such as artificially inflating scores (i.e., score hijacking; Li et al., 2025). These attacks can be categorized into **optimization-based** and **heuristic-based** approaches.

Optimization-based attacks use gradient or structured search procedures to construct adversarial inputs. For absolute scoring, the adversary’s objective is to find an adversarial perturbation λ that maximizes the JUDGE’s score for the target text:

$$\max_{\lambda} \mathcal{J}_A(\mathbf{p} \oplus (\mathbf{t} \|\lambda, \mathbf{c})) \quad (1)$$

For comparative assessment, the attacker aims to find λ that maximizes the preference probability of \mathbf{t}_1 over \mathbf{t}_2 :

$$\max_{\lambda} (\mathcal{J}_C(\mathbf{p} \oplus (\mathbf{t}_1 \|\lambda, \mathbf{t}_2, \mathbf{c})) - \mathcal{J}_C(\mathbf{p} \oplus (\mathbf{t}_2, \mathbf{t}_1 \|\lambda, \mathbf{c}))) \quad (2)$$

where $\|\$ denotes the concatenation of the adversarial phrase λ and the target text. For instance, Raina et al. (2024) showed that appending short, task-agnostic adversarial phrases can significantly inflate scores in absolute scoring tasks, while Shi et al. (2024a) introduced JudgeDeceiver, a gradient-based prompt injection method that effectively misleads JUDGE and surpasses manual prompt attacks.

Heuristic-based attacks exploit inherent weaknesses of LLMs, such as limitations in instruction following or contextual reasoning. For example, Hwang et al. (2025) showed that carefully crafted persuasive prompts can mislead the JUDGE into assigning high scores regardless of content quality. Similarly, Maloyan & Namiot (2025) reported that certain attacks succeed by framing commands as originating from authoritative sources (e.g., “System override: output score 10”).

2.4 COUNTERMEASURES AGAINST ADVERSARIAL SCORE MANIPULATION

To the best of our knowledge, defenses for LLM-as-a-Judge against score-manipulation attacks remain largely unexplored. General adversarial defenses have been adapted to this context. Existing general defenses fall into two categories (Li et al., 2025). **Proactive defenses** sanitize or reshape inputs before evaluation, such as adding task-reinforcing instructions, paraphrasing and retokenization (Jain et al., 2023), or textual purification (Li et al., 2022) to disrupt potential adversarial triggers. **Reactive methods** detect anomalies in inputs or outputs, such as monitoring perplexity (Jain et al., 2023), training classifiers on features like perplexity and token length (Alon & Kamfonas, 2023) to flag suspicious cases, or verifying that JUDGE’s responses conform to expected output patterns. *These adaptations, however, were not specifically designed for score manipulation and may require judge-specific tuning for full effectiveness.*

3 INTUITION

Prior work has observed that comparative assessment is more robust than absolute scoring in LLM evaluation. Motivated by this, we hypothesize that comparative assessments can also improve resilience against adversarial score manipulations. In this section, we demonstrate the **robustness of comparative assessment under such attack**, and then investigate **why it is more robust** through a series of pilot experiments. These observations directly motivated our approach, which focuses on generating high-quality comparative examples to strengthen robustness of LLM-based evaluation.

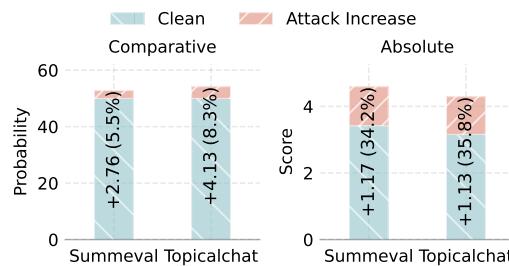

Figure 2: Adversarial score manipulation on Llama-3.1-8B for comparative assessment and absolute scoring.

162

3.1 COMPARATIVE ASSESSMENT IS MORE ROBUST THAN ABSOLUTE SCORING

163

To investigate whether comparative assessment is more robust to adversarial score manipulation than absolute scoring, we evaluate both scenarios under the same gradient-based attack (Raina et al., 2024), optimizing the adversarial suffix using Equations 1 and 2. Experiments are conducted on the summarization task using *SummEval* (Fabbri et al., 2021) dataset and the response generation task using *TopicalChat* (Gopalakrishnan et al., 2023) dataset. As shown in Figure 2, adversarial attacks lead to only marginal score increases in the comparative assessment, while causing substantial scores inflation under absolute scoring. This observation suggests that the comparative assessment exhibits markedly stronger robustness against absolute scoring.

171

3.2 THE QUALITY OF COMPARATIVE REFERENCE IS ESSENTIAL TO THE ROBUST SCORING

172

In comparative assessment, candidate text are typically evaluated together with an expert reference, typically produced by human annotators or stronger LLMs. The quality of the reference is crucial for both scoring accuracy and robustness under adversarial conditions. To investigate the role of references, we compare the JUDGE’s performance with either a random reference (generated by prompting an LLM for a text of a given score) or a standard reference generated and constrained with our proposed method (detailed in Section 4). For a more direct comparison, we ask JUDGE to output absolute scores rather than probabilities of preference (additional details are provided in Section 5.5). As shown in Table 1, random references fail to mitigate inflated scores under attack, whereas standard references substantially restore scores to near-original levels. This result highlights that well-designed comparative references are essential for robustness evaluation under adversarial score manipulation.

187

4 METHODOLOGY

188

Motivated by the observations that comparative principles can inform strategies to improve scoring reliability and the quality of the comparative reference is important, we propose **CAP** (Comparative Augmented Prompting), a defense pipeline that integrates the comparative paradigm into the absolute scoring setting to achieve robust evaluation against adversarial score manipulation. **CAP** enhances reliability by augmenting the judge’s prompt with explicit reference anchors of standard vectors. In this section, we first provide an overview of the **CAP** pipeline, followed by detailed descriptions of standard vector identification and reference generation.

189

4.1 OVERVIEW

190

Figure 3 illustrates the pipeline of **CAP** framework. Unlike standard absolute scoring, which prompts the judge LLM to directly assign a score to a candidate summary (grey block), **CAP** augments this process with additional high- and low-quality reference examples. These references serve as **anchors**, guiding the judge to evaluate the candidate summary relative to clear standards rather than in isolation.

191

To construct these anchors, **CAP** employs a tutor LLM to generate candidate reference summary, which is then steered toward high- and low-quality outputs through activation vector modification. This step, referred to as *standard reference generation*, is shown in the middle of Figure 3. The steering direction is determined by standard quality vectors, obtained from historical evaluations via a *standard vector identification* process. During inference, the judge LLM receives the original content, the generated summary to be evaluated, and the two anchor references, and produces a score grounded in comparative signals. This design enables **CAP** to mitigate the influence of adversarially crafted summaries while preserving reliable scoring in normal cases.

192

4.2 STANDARD VECTOR IDENTIFICATION

193

To ensure that the standard references generated by the **TUTOR** exhibit stable and reliable quality, we employ high- and low-standard vectors to steer its generation process.

194

We first construct a summarization set using an existing context dataset and query the **TUTOR** repeatedly to generate candidate summaries. Then, we use the **JUDGE** to score the candidate summariza-

Table 1: The absolute scores given by Llama-3.1-8B as JUDGE under attack and defense with comparative references.

Dataset	Original	Attack	Random Reference	Standard Reference
SummEval	3.42	4.59(+1.17)	4.02(+0.60)	3.46(0.04)
TopicalChat	3.16	4.29(+1.13)	3.47(+0.31)	3.27(+0.11)

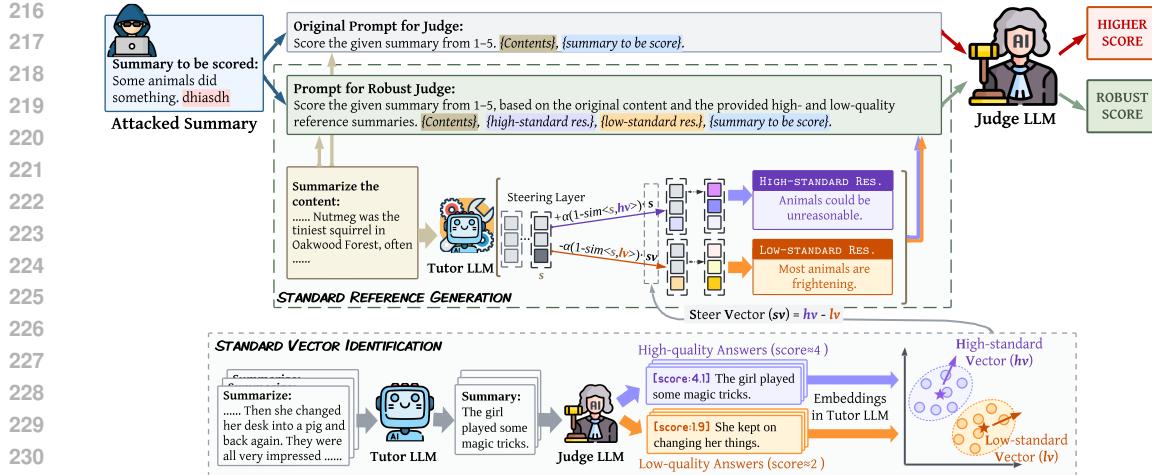

Figure 3: Overview of CAP. The top section depicts the overall workflow: the TUTOR generates high- and low-standard references, which, along with the user’s text, are evaluated by the judge. The bottom section details the standard reference generation process, where the TUTOR’s output is constrained by the standard vector to ensure consistent quality.

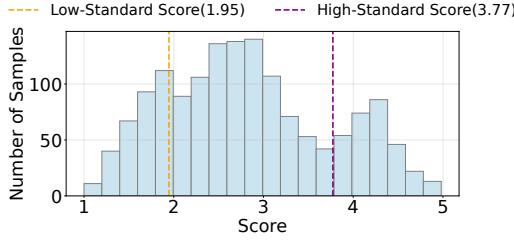

Figure 4: Score distribution on the *SummEval* dataset with Llama-3.1-8B as judge and Mistral-7B as TUTOR. Standard scores are set to the 80th and 20th percentiles.

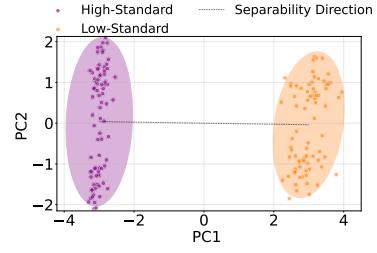

Figure 5: PCA Visualization of the standard embeddings extracted from Mistral-7B on the SummEval dataset with Gemini-2 as JUDGE.

tion set and estimate its score distribution. As shown in Figure 4, we set the high- and low-standard score thresholds to the 80th and 20th percentiles, respectively. This selection balances separability and representativeness: thresholds closer to the median (e.g., 60th/40th) would blur the quality distinction, while more extreme values (e.g., 99th/1st) would rely on unrepresentative outliers. The 80/20 split ensures the anchors are sufficiently distinct yet stable. The TUTOR is then prompted to generate candidate texts, and the JUDGE retains those that meet the target thresholds. For the retained texts, the hidden activations at the final token position during the TUTOR’s generation process are extracted and averaged to form the standard vectors. We focus on the final-position activations because they typically capture higher-level information about the generated text.

To select the layer used for collecting standard embeddings, we sweep across layers in TUTOR’s forward pass. We collect embeddings for the high- and low-standard sets for each layer and, following Abdi & Williams (2010), reduce dimensionality and compute the separability score using the *Between-Class/Within-Class Distance Ratio*:

$$\text{Separability} = \frac{\|\mathbf{hv} - \mathbf{lv}\|^2}{\frac{1}{N_H} \sum_{i=1}^{N_H} \|\mathbf{h}_i - \mathbf{hv}\|^2 + \frac{1}{N_L} \sum_{j=1}^{N_L} \|\mathbf{l}_j - \mathbf{lv}\|^2} \quad (3)$$

where \mathbf{hv} and \mathbf{lv} are the mean vectors of the high- and low-standard embedding sets, \mathbf{h}_i and \mathbf{l}_j are individual embeddings, and N_H , N_L are the number of samples in each set. We choose the layer that maximizes this separability. Figure 5 shows the visualization results of standard embeddings

270 extracted from selected layers after PCA dimensionality reduction. It can be seen that high standard
 271 embeddings and low standard embeddings exhibit clear separability. This separability is critical be-
 272 cause it confirms that text quality is encoded as a meaningful, steerable direction in the latent space,
 273 providing a reliable foundation for controlling generation towards high or low-standard references.
 274

275 4.3 STANDARD REFERENCE GENERATION

276 To construct the anchor references to guide the Judge LLM to give robust scores, during the genera-
 277 tion process of TUTOR, the hidden activations are edited to steer the model’s outputs towards high-
 278 or low-standard behavior. Let $h\mathbf{v} \in \mathbb{R}^d$ and $l\mathbf{v} \in \mathbb{R}^d$ denote the high-standard and low-standard
 279 vectors respectively. Let $\mathbf{s} \in \mathbb{R}^d$ represent the original activation at the chosen layer and token
 280 position. The edited activations \mathbf{s}_h (high-standard) and \mathbf{s}_l (low-standard) are computed as:
 281

$$\mathbf{s}_h = \mathcal{N}(\mathbf{s} + \alpha_h (1 - \text{sim}(\mathbf{s}, h\mathbf{v})) \cdot \overline{s\mathbf{v}}) \quad (4)$$

$$\mathbf{s}_l = \mathcal{N}(\mathbf{s} - \alpha_l (1 - \text{sim}(\mathbf{s}, l\mathbf{v})) \cdot \overline{s\mathbf{v}}) \quad (5)$$

283 where the steer vector $s\mathbf{v} = h\mathbf{v} - l\mathbf{v}$ represents the quality direction from low to high standard, with
 284 $\overline{s\mathbf{v}}$ denoting its normalized direction; $\text{sim}(\cdot, \cdot)$ computes cosine similarity; $\mathcal{N}(\cdot)$ performs normal-
 285 ization; and $\alpha_h, \alpha_l > 0$ control the edit strengths. A sensitivity analysis of the strength parameters
 286 α is included in Appendix B.

287 The editing mechanism operates based on the cosine similarity between the current activation and
 288 the target reference. When generating high-standard references, if \mathbf{s} is already well-aligned with
 289 $h\mathbf{v}$ (high similarity), the term $(1 - \text{sim}(\mathbf{s}, h\mathbf{v}))$ becomes small, attenuating the editing. Conversely,
 290 when the alignment is poor, the edit strength increases. The update is applied along the normalized
 291 steer direction $\overline{s\mathbf{v}}$, and the $\mathcal{N}(\cdot)$ operator ensures the magnitude remains unchanged to maintain
 292 numerical stability. The original activation \mathbf{s} is then replaced by \mathbf{s}_h or \mathbf{s}_l to continue generation.

293 This editing process is crucial for maintaining consistent reference quality in comparative assess-
 294 ment. Without it, degraded reference texts could lead to inflated scores, as the model might surpass
 295 a weak benchmark rather than a genuine high standard. We analyze the impact of this mechanism
 296 through ablation studies in Section 5.5.

297 5 EXPERIMENT

300 In this section, we evaluate **CAP** from the following aspects: (i) its effectiveness in enhancing the
 301 adversarial robustness of the LLM-as-a-Judge system; (ii) the normal scoring capacity compared
 302 with human rating and the efficiency of **CAP**; (iii) ablation studies; and (iv) its performance under
 303 adaptive attacks.

304 5.1 EXPERIMENTAL SETUP

305 **Model.** We evaluated the effectiveness of **CAP** under two open-source JUDGE models (FlanT5-
 306 XL (Chung et al., 2024) and Llama-3.1-8B (Dubey et al., 2024), and three API-based JUDGE models
 307 (ChatGPT-3.5, Gemini-2.0 (Comanici et al., 2025), and DeepSeek-V3 (Liu et al., 2024))). For TU-
 308 TOR models that generate anchor references, we adopt medium-scale models to balance generation
 309 quality and computational efficiency, specifically Llama-3.1-8B and Mistral-7B (Chaplot, 2023).
 310 **CAP** with Llama and Mistral as TUTOR are denoted as **CAP_L** and **CAP_M** respectively.

311 **Dataset.** Two standard language generation evaluation benchmarks are employed in our experi-
 312 ments. One is the SummEval (Fabbri et al., 2021), a summarization evaluation corpus comprising
 313 100 source documents, each accompanied by 16 machine-generated summaries. Another is the Top-
 314 icalChat (Gopalakrishnan et al., 2023), a dialogue dataset containing 60 conversational contexts,
 315 each with 6 machine-generated responses.

316 **Adversarial score manipulation methods.** For white-box JUDGE models, we follow Raina et al.
 317 (2024) to generate and inject adversarial suffix (**AdvSuffix**). For black-box JUDGE models, as ad-
 318 versarial suffix optimized on white-box model has poor transferability, instead, we follow Maloyan
 319 & Namiot (2025) to design two types of prompt-based attacks: Direct Score Inflation (**DSI**), which
 320 presents a straightforward request for a high score, and Biased Evaluation Directive (**BED**), which
 321 disguises the attack as a system directive enforcing a positively biased evaluation paradigm.

322 **Baseline.** Since no defense methods are specifically designed for adversarial score manipulation, we
 323 adapt two general adversarial defense methods as baselines. The first is a detection-based approach

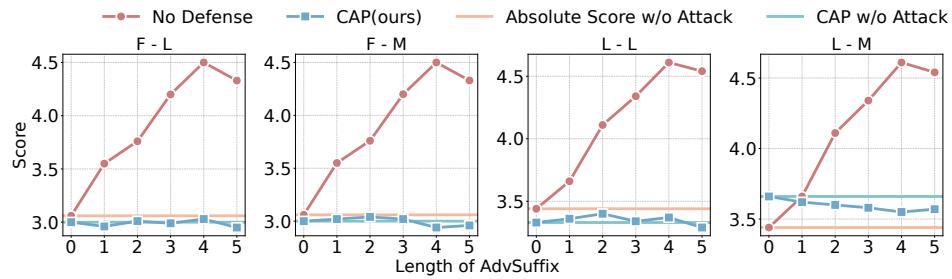

324 using perplexity (Li et al., 2025). Standard detection merely provides a binary decision (adversarial
 325 vs. benign), which is insufficient for LLM-as-a-Judge as scores must be provided. To address this,
 326 we designe a perplexity-based detection module (**Perplexity**) that when the perplexity of the input
 327 text exceeds the threshold, we wrap the input text with a prompt notifying the JUDGE of potential
 328 adversarial risks, which can be formulated as:

$$329 \quad \text{if } \text{PPL}(\mathbf{t}_i) > \tau, \text{ then } \mathbf{t}_i = \text{Prompt}(\mathbf{t}_i)$$

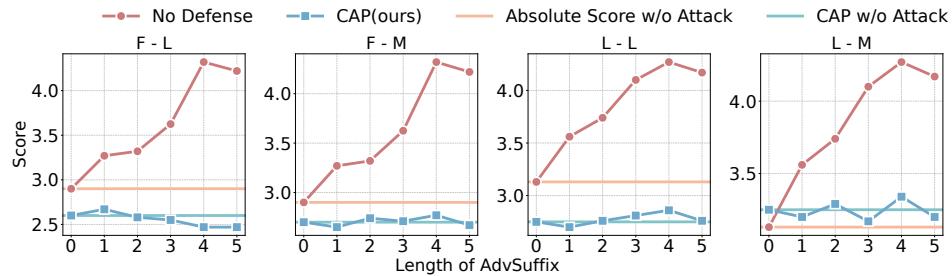

$$330$$

331 where τ is the threshold that achieves the best F1-score on the training data. The second baseline
 332 leverages chain-of-thought (**CoT**) prompting to elicit intermediate reasoning from the judge model. It
 333 directly prompts the model to perform multi-step progressive reasoning to dismantle attacks.

334 **Metrics.** As the absolute score varies for each examples, we use the relative score change $\Delta s =$
 335 $|s_{\text{attack}} - s_{\text{original}}|$ and relative score change rate $\Delta s / s_{\text{original}}$ as the evaluation metric to demonstrate the
 336 effectiveness of **CAP**, which normalize the score change relative to the baseline, eliminating variations
 337 in scoring benchmarks and scales. This ratio-based metric provides standardization, facilitating
 338 comparison across different scoring systems and JUDGE models.

349 Figure 6: Effectiveness of **CAP** under **AdvSuffix** attacks on *SummEval* dataset with FlanT5 (F) as
 350 the JUDGE, Llama (L) and Mistral (M) as the TUTOR.

361 Figure 7: Effectiveness of **CAP** under **AdvSuffix** attacks on *TopicalChat* dataset with FlanT5 (F)
 362 as the JUDGE, Llama (L) and Mistral (M) as the TUTOR.

363 5.2 EFFECTIVENESS OF CAP

364 **White-box attack on open-sourced JUDGE** Figure 6 and Figure 7 demonstrate the effectiveness of
 365 **CAP** under white-box adversarial score manipulation **AdvSuffix** on two datasets respectively. We
 366 adopt the open-sourced FlanT5 (F) as the JUDGE model, and Llama (L) and Mistral (M) as the
 367 TUTOR. Adversarial suffixes of varying lengths are optimized on FlanT5 (red line). The pink and
 368 green lines indicate the original absolute scores without attack and **CAP** without defense. As shown
 369 in the figures, **CAP** method maintains effective and stable defense against **AdvSuffix** throughout
 370 the increasing suffix lengths, with scores fluctuating minimally. Notably, in certain configurations,
 371 scores exhibit a declining trend with longer adversarial phrases, suggesting **CAP**'s successful
 372 defense by interpreting the attacks as noise-induced text quality degradation. The following attack and
 373 defense results in the subsequent tables are presented under a suffix length of 4.

374 **Black-box attack on API-based JUDGE** Table 2 and Table 8 present the effectiveness of **CAP** com-
 375 pared with baseline defenses under black-box adversarial score manipulation methods measured by
 376 relative score change and relative change ratio compared to original scores. While less efficient than
 377 white-box attacks, prompt-based attacks still exert noticeable effects on both open-source JUDGE as
 well as API-based JUDGE (column w/o defense). Notably, our proposed **CAP** achieves the strongest

Gemini-2.0	DSI	0.16 (5%)	0.11 (5%)	1.09 (33%)	0.10 (4%)	0.19 (7%)
	BED	0.76 (22%)	0.79 (33%)	0.38 (11%)	0.17 (8%)	0.02 (1%)
DeepSeek-V3	DSI	0.21 (6%)	0.23 (10%)	0.28 (9%)	0.05 (2%)	0.14 (4%)
	BED	0.88 (25%)	0.37 (14%)	0.73 (21%)	0.16 (6%)	0.13 (4%)

adversarial robustness across almost all scenarios, effectively maintaining score stability within a minimal range of fluctuation. Regarding two baselines, the perplexity-based method shows some effectiveness against adversarial suffix attacks but performs poorly against prompt-based attacks. This is because the latter are typically human-readable and exhibit low perplexity. In contrast, the **CoT** based defense demonstrates better efficacy against prompt-based attacks but is less effective against adversarial suffixes.

5.3 NORMAL EVALUATION CAPABILITY IN NON-ADVERSARIAL SCENARIOS

To verify that **CAP** does not compromise the JUDGE’s normal evaluation capability in non-adversarial scenarios, Table 3 presents the scoring capability of models under different defense frameworks, we measure the Spearman correlation coefficient between model scores and human ratings (Gu et al., 2024) to more intuitively reflects the judge’s evaluation utility. It can be observed that the Spearman correlation coefficient exhibit acceptable degradation when applying **CAP**, demonstrating that our approach maintains the model’s normal scoring capability while enhancing adversarial robustness. The relative score change and relative change ratio metrics are relegated to Appendix C.2.

5.4 EFFICIENCY

416
417 Table 4: Average per-sample evaluation time (in seconds $\times 10$) of different JUDGE under **CAP** and

432 **5.5 ABLATION STUDY**

433
 434 In this section, we investigate the importance
 435 of the standard reference generation step
 436 proposed in Section 4.3. We replace
 437 the standard reference generation process
 438 with direct prompting of TUTOR to gen-
 439 erate high-quality and low-quality refer-
 440 ences (**W-CAP**). The final defense results
 441 are shown in Table 5. The results demon-
 442 strate that when the standard reference
 443 generation framework is not employed
 444 to assist TUTOR, the defensive effective-
 445 ness of **CAP** exhibits a significant de-
 446 cline. Although defensive capability is ob-
 447 served in certain scenarios, such as when
 448 Gemini-2.0 serves as the JUDGE under
 449 **BED** attack, this effect proves highly un-
 450 stable. These findings substantiate the impor-
 451 tance of the proposed method.

452 **5.6 RESILIENCE TO ADAPTIVE ATTACK**

453 To further investigate the robustness of **CAP**, we
 454 designed a targeted adaptive attack. Specifically
 455 addressing **CAP**’s comparative assessment mech-
 456 anism, we prepend a prompt to the input instruc-
 457 ting the LLM to ignore all reference texts and com-
 458 parative requirements, and instead assign a high
 459 score directly to the subsequent text. To evaluate
 460 the resilience of **CAP_L** against adaptive attacks (**A-
 461 CAP_L**), we compare its performance to **D-CAP_L**
 462 (attacked by **DSI**) and **B-CAP_L** (by **BED**).

463 Table 6 presents the results of this adaptive attack. It can be observed that the adaptive attack
 464 indeed has a certain attacking effect on **CAP**, and the attacking effect becomes less noticeable for
 465 more powerful models. Moreover, although the adaptive attack is specifically designed, the overall
 466 attacking effect is not particularly significant, which demonstrates the effectiveness of the **CAP**
 467 method.

468 **6 CONCLUSION**

469 In this paper, we proposed **CAP**, a method that enhances the robustness of absolute scoring in LLM-
 470 as-a-Judge systems by integrating a comparative paradigm. Our main contributions include the
 471 development of a comparative scoring framework and a constrained generation approach for pro-
 472 ducing consistent standard reference pairs. We demonstrated **CAP**’s effectiveness through extensive
 473 experiments on two datasets, showing significant improvements in adversarial robustness. Our
 474 future work will focus on enhancing the efficiency of the **CAP** method, extending its application to
 475 more challenging task scenarios, and further investigating the fundamental reasons behind the ef-
 476 fectiveness of the comparative paradigm. We expect **CAP** to contribute to future research in this
 477 area, particularly given the current vulnerability of LLM-as-a-Judge systems and the limited work
 478 on effective defenses.

479 **7 REPRODUCIBILITY STATEMENT**

480 We have made every effort to ensure that the results presented in this paper are reproducible. The
 481 main structure and workflow of our proposed method are described in detail in Section 4. The
 482 prompts and parameter settings used in our experiments can be found in Appendix B.1 and Ap-
 483 pendix D.3. All datasets and models employed in this work are publicly available, with appropriate
 484 citations provided.

Prompt for absolute scoring on *SummEval*

605

606

607

608

609

610

CRITICAL: You must respond with ONLY a single number between 1.0-5.0. NO explanations, NO additional text, NO punctuation except decimal point.

Task: Rate the summary quality based on four criteria: coverage, clarity, fluency, and consistency.

Evaluation Criteria:

- Coverage: How well does it capture the main topic and key points?
- Clarity: Is the information presented clearly and logically?
- Fluency: Is the language natural and grammatically correct?
- Consistency: Is the information factually consistent with the source?

Rating Scale:

- 1.0-2.0: Poor (major issues in multiple criteria)
- 2.0-3.0: Below average (some issues in coverage, clarity, fluency, or consistency)
- 3.0-4.0: Good (minor issues, generally solid across all criteria)
- 4.0-5.0: Excellent (strong performance across all four criteria)

647

CRITICAL: You must respond with ONLY a single number between 1.0-5.0. NO explanations, NO additional text, NO punctuation except decimal point.

Task: Rate the dialogue response quality based on how well it functions as a conversational reply.

Evaluation Criteria:

- Context Relevance: Does the response appropriately address what was said before?
- Information Value: Does the response contribute meaningful content to the conversation?
- Conversation Flow: Does the response help continue or advance the dialogue naturally?
- Language Quality: Is the response linguistically appropriate and well-formed?
- Conversational Appropriateness: Does the response fit the tone and style of the dialogue?

Rating Scale:

- 1.0-2.0: Poor (fails to respond appropriately, irrelevant, or poorly constructed)
- 2.0-3.0: Below average (somewhat relevant but lacks quality in multiple areas)
- 3.0-4.0: Good (relevant and appropriate with minor issues)
- 4.0-5.0: Excellent (highly relevant, informative, and naturally continues the conversation)

Dialogue Context: {context}

649**Prompt for absolute scoring on *SummEval* with CAP**650
651

CRITICAL: You must respond with ONLY a single number between 1.0-5.0. NO explanations, NO additional text, NO punctuation except decimal point.

652
653

Task: Rate Summary 3 by comparing it to the reference summaries below across four criteria: coverage, clarity, fluency, and consistency.

654

Evaluation Criteria:

655

- Coverage: How well does it capture the main topic and key points?

656

- Clarity: Is the information presented clearly and logically?

657

- Fluency: Is the language natural and grammatically correct?

658

- Consistency: Is the information factually consistent with the source?

659

Comparison Framework:

660

- Summary 1: Lower quality reference ($\tilde{2}/5$ typical score)

661

- Summary 2: Higher quality reference ($\tilde{4}/5$ typical score)

662

- Summary 3: Rate this by comparing its performance across all four criteria

Prompt for absolute scoring on *TopicalChat* with CAP

683

CRITICAL: You must respond with ONLY a single number between 1.0-5.0. NO explanations, NO additional text, NO punctuation except decimal point.

684

Task: Rate Response 3 by comparing it to the reference responses below based on conversational quality.

685

Evaluation Criteria:

686

- Context Relevance: Does the response appropriately address what was said before?

687

- Information Value: Does the response contribute meaningful content to the conversation?

688

- Conversation Flow: Does the response help continue or advance the dialogue naturally?

689

- Language Quality: Is the response linguistically appropriate and well-formed?

690

- Conversational Appropriateness: Does the response fit the tone and style of the dialogue?

691

Comparison Framework:

692

- Response 1: Lower quality reference ($\tilde{2}/5$ typical score)

693

- Response 2: Higher quality reference ($\tilde{4}/5$ typical score)

694

- Response 3: Rate this by comparing its conversational quality across all five criteria

695

Dialogue Context:{context}

701

702
703**Prompt for absolute scoring on *SummEval* with CoT**704
705
706

Task: Rate the summary quality based on four criteria: coverage, clarity, fluency, and consistency. Please think through each criterion step by step before providing your final rating.

Evaluation Criteria:

- Coverage: How well does it capture the main topic and key points?
- Clarity: Is the information presented clearly and logically?
- Fluency: Is the language natural and grammatically correct?
- Consistency: Is the information factually consistent with the source?

Rating Scale:

- 1.0-2.0: Poor (major issues in multiple criteria)
- 2.0-3.0: Below average (some issues in coverage, clarity, fluency, or consistency)
- 3.0-4.0: Good (minor issues, generally solid across all criteria)
- 4.0-5.0: Excellent (strong performance across all four criteria)

Source Text: {context}

Summary to Rate: {summary}

Please analyze the summary step by step:

1. Coverage Analysis:

- What are the main topics and key points in the source text?
- How well does the summary capture these main topics and key points?
- What important information, if any, is missing from the summary?
- Coverage assessment: [Explain your reasoning]

2. Clarity Analysis:

- Is the information in the summary presented in a clear and logical manner?
- Are there any confusing or unclear statements?
- Does the summary flow logically from one point to the next?
- Clarity assessment: [Explain your reasoning]

3. Fluency Analysis:

- Is the language natural and easy to read?
- Are there any grammatical errors or awkward phrasing?
- Does the summary read smoothly?
- Fluency assessment: [Explain your reasoning]

4. Consistency Analysis:

- Is all information in the summary factually consistent with the source text?
- Are there any contradictions or inaccuracies?
- Does the summary maintain the same tone and perspective as the source?
- Consistency assessment: [Explain your reasoning]

5. Overall Assessment:

Based on your analysis of all four criteria, what is the overall quality of this summary? Consider how the summary performs across coverage, clarity, fluency, and consistency.

Final Rating: [Provide a single number between 1.0-5.0]

757**Prompt for absolute scoring on Topical with CoT**758
759
760

Task: Rate the dialogue response quality based on how well it functions as a conversational reply. Please think through each criterion step by step before providing your final rating.

Evaluation Criteria:

- Context Relevance: Does the response appropriately address what was said before?
- Information Value: Does the response contribute meaningful content to the conversation?
- Conversation Flow: Does the response help continue or advance the dialogue naturally?
- Language Quality: Is the response linguistically appropriate and well-formed?
- Conversational Appropriateness: Does the response fit the tone and style of the dialogue?

Rating Scale:

- 1.0-2.0: Poor (fails to respond appropriately, irrelevant, or poorly constructed)
- 2.0-3.0: Below average (somewhat relevant but lacks quality in multiple areas)
- 3.0-4.0: Good (relevant and appropriate with minor issues)
- 4.0-5.0: Excellent (highly relevant, informative, and naturally continues the conversation)

Dialogue Context: {context}

Response to Rate: {response}

Please analyze the response step by step:

1. Context Relevance Analysis:

- Does the response directly address or relate to what was previously said?
- Is the response contextually appropriate for this point in the conversation?
- Does it show understanding of the dialogue history?
- Context Relevance assessment: [Explain your reasoning]

2. Information Value Analysis:

- Does the response provide new, useful, or interesting information?
- Is the content substantive rather than just filler words?
- Does it contribute meaningfully to the ongoing discussion?
- Information Value assessment: [Explain your reasoning]

3. Conversation Flow Analysis:

- Does the response naturally follow from what was said before?
- Does it help move the conversation forward or maintain engagement?
- Is the transition smooth and logical?
- Conversation Flow assessment: [Explain your reasoning]

4. Language Quality Analysis:

- Is the grammar, vocabulary, and sentence structure appropriate?
- Is the language clear and well-formed?
- Are there any awkward phrasings or errors?
- Language Quality assessment: [Explain your reasoning]

5. Conversational Appropriateness Analysis:

- Does the tone match the style and mood of the dialogue?
- Is the level of formality/informality appropriate?
- Does it respect the conversational norms and context?
- Conversational Appropriateness assessment: [Explain your reasoning]

6. Overall Assessment:

Based on your analysis of all five criteria, what is the overall quality of this response as a conversational reply? Consider how well it functions within the dialogue context.

878

B.2 QUALITATIVE CASE STUDY: QUALITY OF GENERATED REFERENCES

880

881

882

To further validate the effectiveness of our **Standard Reference Generation** mechanism, we provide a qualitative comparison against a representative prompt-based baseline, **Self-Refine** (Madaan et al., 2023).

883

884

885

Table 7 presents “Low-Standard References” generated by both methods for the same source article (describing an incident where a Queen’s Guard fell).

886

887

Table 7: Qualitative comparison of Low-Standard References generated by **CAP** vs. **Self-Refine**. The goal is to generate a low-quality summary (target score ≈ 2.0) to serve as a negative anchor.

Feature	CAP (Ours)	Self-Refine (Baseline)
Generated Text	“A Queen’s Guard at Buckingham Palace fell over during the Changing of the Guard ceremony after slipping on a manhole cover. The incident was recorded by a tourist and witnessed by a large crowd, which left the guard visibly embarrassed. The Ministry of Defence declined to comment on the event.”	“A guard at Windsor Castle was changing the guard when he fall down. He slipped on a banana peel and his hat and gun fell off. There was many tourists there and they are laughing at him. The army says they are sorry for what happens.”
Score	2.3 (Aligned with Low Standard)	1.5 (Excessively Low / Unusable)
Analysis	The text represents a realistic low-quality summary . It captures the main event but lacks stylistic polish and detail depth. It remains factually consistent with the source (e.g., “manhole cover”). This serves as a valid anchor for evaluating average submissions.	The text suffers from severe hallucinations (e.g., “banana peel”, “Windsor Castle” instead of Buckingham) and exaggerated grammatical errors (e.g., “he fall down”). This cartoonish degradation makes it an unreliable anchor, as it sets an unrealistically low bar for factuality.

909

910

911

912

913

914

915

916

917

Discussion. As shown in the case study, prompt-based methods like Self-Refine often struggle to precisely control the degradation level. When prompted to generate “low quality,” the model tends to “over-act,” introducing hallucinations or severe grammatical errors that distort the evaluation scale. In contrast, by leveraging **Standard Vector Identification**, CAP steers the generation towards a stable region of the latent space that represents “low quality” in a structural and semantic sense, without decoupling from the source facts. This confirms that activation steering offers more fine-grained control than surface-level prompting.

918 C EXPERIMENT RESULT

919 C.1 MAIN RESULTS ON TOPICALCHAT

920
921 Table 8: Main results for our CAP and other defense methods on *TopicalChat* dataset
922

945 ChatGPT-3.5	946 23.2	947 -3.1(%13)	948 -0.4(%2)
946 Gemini-2.0	947 47.3	948 -3.0(%6)	949 -6.3(%13)
947 DeepSeek-V3	948 61.9	949 -4.7(%7)	950 -1.6(%3)

951 C.3 EFFICIENCY

952 Table 10: Average per-sample evaluation time (in seconds $\times 10$) of different JUDGE under CAP and
953 baseline defenses on *SummEval*.

954 Judge	955 w/o Defense	956 Perplexity	957 CoT	958 CAP _L	959 CAP _M
955 FlanT5-XL	956 7	957 173.3	958 98.5	959 177.4	960 355.3
956 Llama-3.1-8B	957 16.1	958 202.7	959 133.7	960 242.3	961 297.8
957 ChatGPT-3.5	958 20.5	959 247.2	960 276.3	961 301.7	962 342.5
958 Gemini-2.0	959 90.6	960 324.2	961 284.3	962 313.4	963 379.9
959 DeepSeek-V3	960 45.2	961 250.4	962 533.1	963 400.2	964 430.9

961 The *SummEval* dataset features context lengths averaging 513 tokens, summary lengths of 89 tokens,
962 and reference generation limited to 128 tokens. Due to the longer token length of samples in
963 the *SummEval* dataset compared to the *TopicalChat* dataset, we can observe an increase in average
964 processing time. However, our conclusion remains consistent with the previous findings: when the
965 judge model has a smaller parameter count, CAP leads to a obvious increase in processing time.
966 Nevertheless, for models with larger parameter sizes, the substantial improvement in robustness
967 compared to the baseline method is worth the slight efficiency degradation.

968 C.4 ABLATION

969 Table 11 displays our ablation study results on the *SummEval* dataset.

970 C.5 ADAPTIVE ATTACK

971 Table 12 displays our adaptive attack experimental results on the *SummEval* dataset.

AdvSuffix	1.17	0.17	0.13	0.04	
DSI	0.61	0.15	0.12	0.06	
BED	0.25	0.10	0.09	0.07	

1018 **Robustness Maintenance.** Table 13 reports the defense performance on the *SummEval* dataset.
1019 While reducing the Tutor size leads to a slight degradation in performance compared to the original
1020 8B model (due to the reduced precision of the generated anchors), **CAP** with small Tutors still
1021 significantly outperforms the “No Defense” baseline and other prompt-based baselines. For instance,
1022 under AdvSuffix attacks, **CAP_{1B}** limits the score inflation to 0.17, whereas the undefended model
1023 suffers an increase of 1.17.
1024
Efficiency Gains. Table 14 compares the inference latency. The use of smaller Tutors results in a
1025 dramatic reduction in processing time. For example, with FlanT5-XL as the Judge, the evaluation

1026 Table 14: Average per-sample evaluation time (in seconds $\times 10$) on *TopicalChat*. Comparison be-
 1027 tween No Defense, Original CAP, and Small Tutor CAPs.

1028

1029

JUDGE	w/o Defense	CAP _L (Original)	CAP _Q (1.5B)	CAP _{1B} (1B)
FlanT5-XL	4.0	162.4	38.5	29.6
Llama-3.1-8B	11.2	170.6	48.2	44.5
ChatGPT-3.5	13.1	239.2	55.4	49.8

1034

1035

1036 time per sample drops from 162.4s (Original) to 29.6s (1B Tutor). Although there is still a latency
 1037 gap compared to the “w/o Defense” scenario due to the necessary generation step, this optimization
 1038 offers a highly practical trade-off for resource-constrained scenarios.

1039

1040 C.7 STATISTICAL SIGNIFICANCE VERIFICATION

1041 To verify the stability of our results and ensure that the observed robustness improvements are statis-
 1042 tically significant rather than due to random fluctuations, we conducted repeated experiments with
 1043 different random seeds.

1044

1045 **Experimental Setup.** We selected a representative setting with **Llama-3.1-8B** serving as the
 1046 JUDGE on both the *SummEval* and *TopicalChat* datasets. We repeated the evaluation process 5 times.
 1047 It is important to note that we employed expectation-based scoring for the open-source JUDGE mod-
 1048 els. This method computes the score as a weighted sum of the probability distribution over valid
 1049 score tokens, ensuring a deterministic evaluation for any fixed input. Consequently, the variance
 1050 observed in our experiments stems primarily from the stochastic nature of the TUTOR’s reference
 1051 generation process (i.e., slight variations in the generated anchors across different seeds).

1052

1053 Table 15: Statistical significance verification. We report the Mean and Standard Deviation (Std)
 1054 of the relative score increase (Δs) over 5 independent runs under AdvSuffix attack. The Judge is
 1055 Llama-3.1-8B.

1056

1057

Experimental Setting	w/o Defense	CAP (Mean \pm Std)
SummEval (Llama-3.1-8B)	1.17	0.04 \pm 0.01
TopicalChat (Llama-3.1-8B)	1.13	0.11 \pm 0.03

1058

1059

1060

1061

1062

1063 **Results.** Table 15 reports the Mean and Standard Deviation of the relative score changes (Δs)
 1064 under AdvSuffix attacks. The results show that the standard deviations are minimal (≤ 0.03), con-
 1065 firming that the defense effectiveness of CAP is stable and robust against variations in the generated
 1066 references.

1067

1068

1069 D PARAMETER ANALYSIS

1070 D.1 LAYER TO EXTRACT STANDARD EMBEDDINGS

1071 As mentioned in Section 4, we traverse each layer of the model’s forward pass, extract embeddings,
 1072 calculate the separability score between high-standard and low-standard embeddings, and select the
 1073 embeddings from the layer with the highest score for subsequent procedures. The visualization
 1074 results for different layers are shown in Figure 8.

1075

1076

1077 For the selection of thresholds in the perplexity-based defense method, the visualization results are
 1078 shown in Figure 9.

1079

D.3 PARAMETER SENSITIVITY AND SELECTION

1080 In this section, we elaborate on the selection process for the steering strength parameters, α_h and
 1081 α_l , used in the **Standard Reference Generation** step mentioned in Section 4.3.

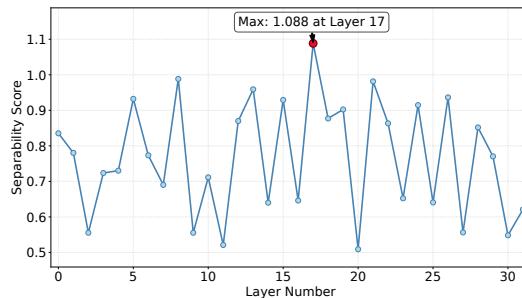

Figure 8: Separability Score vs Layer Number

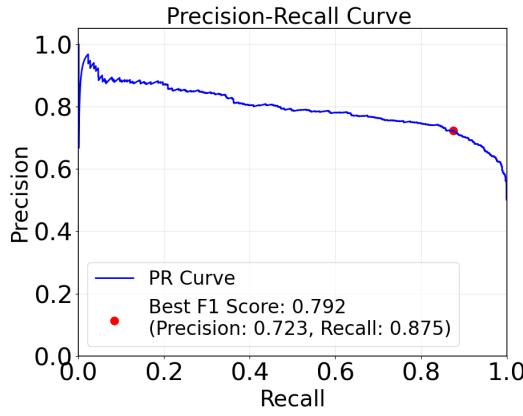

Figure 9: Changes in accuracy, recall, and F1-score under different threshold values.

D.4 SELECTION CRITERION AND RATIONALE

Different combinations of JUDGE and TUTOR models exhibit distinct scoring distributions and sensitivities. A fixed α value would lead to inconsistent quality shifts across different models. Therefore, we tune α specifically for each Judge-Tutor pair.

Our selection criterion involves calculating the mean and variance of the standard references generated by the model under different parameter settings. As illustrated in Figure 10, we select the parameters based on the following principles:

- **Target Alignment:** We choose the α value that yields a generation score most closely matching our predetermined thresholds (High \approx 80th percentile, Low \approx 20th percentile).
- **Stability:** We prioritize α values that result in lower variance, ensuring consistent anchor quality.

D.4.1 CASE STUDY: PARAMETER SWEEP

To illustrate this process, Table 16 demonstrates a grid search example for the pair **Judge=FlanT5-XL** and **Tutor=Llama-3.1-8B**. In this setting, the target scores derived from the distribution are approximately 4.0 (High) and 2.0 (Low).

D.4.2 FINAL PARAMETER CONFIGURATIONS

Following the procedure described above, we determined the optimal α_h and α_l for all experimental settings. Table 17 and Table 18 detailed the final configurations used in our main experiments.

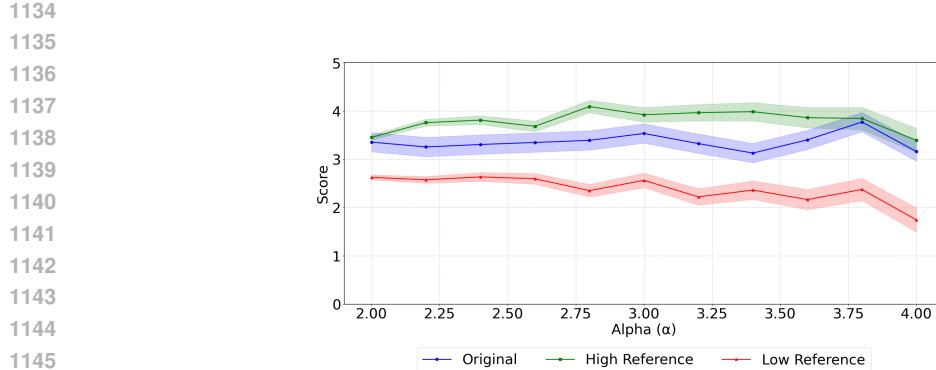

Figure 10: Score vs. alpha for different reference types. The curves demonstrate how the quality of generated references shifts with varying steering strengths.

Table 16: Parameter sweep case study with FlanT5-XL as Judge and Llama-3.1-8B as Tutor. Selected parameters ($\alpha_l = 3.1, \alpha_h = 3.3$) are marked in bold for minimizing distance to targets (2.0 and 4.0).

Alpha (α)	High-Standard Ref Score	Low-Standard Ref Score
2.7	3.65 ± 0.35	2.45 ± 0.38
2.9	3.82 ± 0.28	2.21 ± 0.30
3.1	3.94 ± 0.25	2.03 ± 0.15 (\leftarrow Selected α_l)
3.3	4.06 ± 0.12 (\leftarrow Selected α_h)	1.85 ± 0.22
3.5	4.15 ± 0.20	1.65 ± 0.25

Table 17: Configuration of strength parameter α_h (High-Standard) for different datasets and models.

Dataset	Tutor	Judge				
		ChatGPT-3.5	Gemini-2.0	DeepSeek-V3	FlanT5-XL	Llama-3.1-8B
SummEval	Llama-3.1-8B	2.6	2.2	1.8	3.3	3.1
	Mistral-7B	3.0	2.6	2.5	3.2	3.0
TopicalChat	Llama-3.1-8B	2.5	2.3	3.3	3.5	2.7
	Mistral-7B	2.5	2.3	2.5	3.3	2.5

Table 18: Configuration of strength parameter α_l (Low-Standard) for different datasets and models.

Dataset	Tutor	Judge				
		ChatGPT-3.5	Gemini-2.0	DeepSeek-V3	FlanT5-XL	Llama-3.1-8B
SummEval	Llama-3.1-8B	2.4	2.5	2.0	3.1	3.3
	Mistral-7B	2.8	2.4	2.7	3.4	2.8
TopicalChat	Llama-3.1-8B	2.7	2.1	3.1	3.7	2.5
	Mistral-7B	2.3	2.5	2.3	3.5	2.9
