## Abstract

Language models have demonstrated important advancements across various natural language processing (NLP) tasks. However, the availability of high-quality and domain-specific data remains a challenge for training these models, particularly in industry-specific applications. In this paper, we propose a methodology to fine-tune a large language model (LLM) using a mixture of private company data and open-source data.

Our empirical investigation reveals that combining private and open-source data during the fine-tuning process leads to superior performance, mitigating the risk of overfitting that can occur when training solely on narrow, domain-specific datasets. We observed that incorporating open-source data alongside the private data helps to reduce the distribution shift between the source and target data, effectively acting as a regularizer and enhancing the model's ability to generalize.

Furthermore, we compare the divergence between the private and open-source datasets with the test loss of the fine-tuned model. Our results suggest a correlation between reduced data divergence and improved model performance, indicating that carefully selecting and curating the dataset mixture can be a crucial step in preventing overfitting and ensuring the model's effective adaptation to industry-specific use cases.

This study provides a practical solution for industry-specific adaptation of LLMs, demonstrating how the strategic blending of private and open-source data can unlock the full potential of these models while addressing critical concerns around data privacy and model reliability in real-world applications.

## 1 Introduction

The integration of large language models (LLMs) into industry-specific applications has the potential to transform operations across various sectors, notably in the energy industry. They can automate and enhance tasks such as predictive maintenance, regulatory compliance, and customer service.

The process of fine-tuning on specific industrial data offers

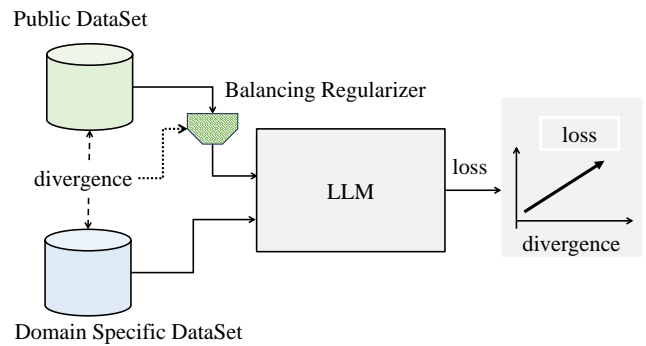

Figure 1: Strategy to use mixture of public dataset and domain specific dataset improves fine tuning of LLM only if divergence between the two dataset is small.

several key advantages:

- **Cost Savings:** Utilizing pre-trained models and fine-tuning them for specific purposes significantly reduces the resources needed for training from scratch. This efficient use of computational power results in considerable cost savings by eliminating the necessity for extensive data collection and expensive hardware procurement for training large models.
- **Privacy and Security:** Fine-tuning enables organizations to customize pre-trained models using their own datasets, keeping sensitive information within the organization and minimizing exposure to external risks. This localized training approach ensures that data remains under the organization's control, protecting privacy and complying with relevant regulations.
- **Tailored Applications:** Fine-tuning opens up possibilities for various specialized applications. For example, chatbots trained on customer service data capable of addressing specific product inquiries, or research assistants fine-tuned on scientific literature to assist researchers in their work.

Moreover, supervised fine-tuning on domain-specific data is advantageous for Retrieval Augmented Generation (RAG)

66 systems [Gao *et al.*, 2023] and becomes a fundamental and  
67 crucial step for improved alignment techniques such as Rein-  
68 forcement Learning from Human Feedback (RLFH) [Ouyang  
69 *et al.*, 2022] and Direct Preference Optimization (DPO)  
70 [Rafailov *et al.*, 2024]. These cutting-edge techniques lever-  
71 age human feedback and oversight to steer LLMs towards  
72 desired behaviors and mitigate potential risks, but their ef-  
73 fectiveness heavily relies on the initial domain-specific fine-  
74 tuning step.

75 Deploying LLMs, including RAG systems, in sectors like en-  
76 ergy, where data are not only domain-specific but also highly  
77 confidential, presents significant challenges [Cuconasu *et*  
78 *al.*, 2024]. Standard fine-tuning practices on such narrow  
79 datasets, especially when the data is substantially out-of-  
80 distribution compared to the training corpus used in the initial  
81 model training, can lead to severe overfitting. This overfitting  
82 hinders the model’s ability to generalize effectively, under-  
83 mining the potential benefits of subsequent alignment tech-  
84 niques and ultimately limiting the model’s practical utility in  
85 industrial settings.

86 This study explores an innovative approach to fine-tuning  
87 LLMs by using a mixed dataset of open-source and propri-  
88 etary domain-specific data. Our empirical results indicate that  
89 this method significantly mitigates overfitting, enabling the  
90 models to generalize better across a broader range of tasks  
91 without compromising data confidentiality. Thus, we provide  
92 a practical solution for industry-specific adaptation of LLMs,  
93 ensuring enhanced performance while adhering to stringent  
94 privacy standards. Crucially, this robust domain-specific fine-  
95 tuning sets the stage for effective application of advanced  
96 alignment techniques, unlocking the full potential of these  
97 models in industrial contexts while addressing critical con-  
98 cerns around safety and reliability.

99 Additionally, our approach enriches the understanding of do-  
100 main adaption in machine learning. In fact, fine-tuning LLMs  
101 on a mixed dataset effectively addresses a domain adaptation  
102 problem where the goal is to adapt the model to fit a mix-  
103 ture of distributions. The integration of open-source data with  
104 the domain specific data reduces the divergence between the  
105 target and source distributions. This strategic blending facil-  
106 itates a more robust training process, helping the model to  
107 better adapt and thus enhancing resilience against overfitting.

## 108 2 Related works

109 The integration of LLMs into domain-specific applications is  
110 a crucial research challenge. For example, the RAG system  
111 is a common strategy to bridge the gap between pre-trained  
112 LLMs and industry-specific data [Cuconasu *et al.*, 2024;  
113 Lewis *et al.*, 2020]. The RAG approach combines the genera-  
114 tive capabilities of LLMs with information retrieval, allowing  
115 the model to access relevant documents and incorporate that  
116 contextual information into its outputs.

117 Recent studies, such as [Cuconasu *et al.*, 2024], demonstrate  
118 the promising results of RAG systems. However, their per-  
119 formance may not be optimal, especially when applied to  
120 domain-specific data. In this case, fine-tuning can improve  
121 the performance of RAG systems in these tasks, or even out-  
122 perform it.

Beyond the RAG system, researchers have explored other 123  
techniques to fine-tune and adapt LLMs to specialized 124  
domains.[Arora *et al.*, 2023] proposed a simplified prompt- 125  
ing strategy that generates multiple questions and aggregates 126  
the most reliable responses, aiming to improve the LLM’s 127  
performance on domain-specific tasks. 128

Recognizing the limitations of pre-trained LLMs in capturing 129  
domain-specific knowledge, researchers have explored hy- 130  
brid approaches that combine the flexibility of LLMs with 131  
enterprise-specific knowledge graphs. [Baldazzi *et al.*, 2023] 132  
demonstrated how this integration of LLMs and ontologi- 133  
cal reasoning can effectively capture and augment domain 134  
knowledge, enhancing the model’s capabilities in industry- 135  
specific applications. 136

Fine-tuning LLMs on large additional text corpora has also 137  
been shown to be effective in improving performance on 138  
various NLP tasks. For example, the FinBERT model 139  
[Liu *et al.*, 2021] was fine-tuned on a financial domain- 140  
specific dataset, leading to improved results on finance- 141  
related tasks. Similarly, [Xia *et al.*, 2024] fine-tuned LLMs 142  
using a manufacturing-domain corpus to better adapt the 143  
models to the nuances of the manufacturing field. 144

However, the lack of available domain-specific training data 145  
remains a significant challenge in many specialized indus- 146  
tries. [Saxena *et al.*, 2024] reported difficulties in finding 147  
appropriate datasets for their domain-specific applications, 148  
highlighting the need for novel approaches to address this 149  
data scarcity. 150

To tackle the data scarcity issue, researchers have explored 151  
parameter-efficient fine-tuning techniques, where only a few 152  
external parameters are fine-tuned instead of the entire LLM 153  
[Hu *et al.*, 2023]. Additionally, data cleaning and curation 154  
approaches, such as the one proposed by Lin *et al.* [Lin *et*  
155 *al.*, 2024], have shown promise in improving the fine-tuning  
156 performance of LLMs. 157

Finally, a comprehensive study by [Zhang *et al.*, 2024] ex- 158  
plored the impact of different scaling factors on the fine- 159  
tuning performance of LLMs, emphasizing the data- and task- 160  
dependent nature of these fine-tuning methods. 161

Overall, the existing literature underscores the importance of 162  
adapting LLMs to domain-specific applications, while also 163  
highlighting the challenges posed by data availability and dis- 164  
tribution shifts. Our work builds upon these insights and pro- 165  
poses a novel approach to fine-tune LLMs using a strategic 166  
mixture of domain-specific and open-source data, with the 167  
aim of mitigating the risk of overfitting and enhancing the 168  
model’s generalization capabilities. 169

## 170 3 Proposed Method

The key challenge we aim to address is the tendency of large 171  
language models (LLMs) to overfit when fine-tuned on lim- 172  
ited, domain-specific data. This phenomenon can lead to poor 173  
generalization, especially on out-of-distribution samples. To 174  
mitigate this issue, we propose a novel fine-tuning approach 175  
that leverages a mixture of data distributions. 176

Our proposed method is motivated by the principles of do- 177  
main adaptation. When fine-tuning an LLM, the target data 178  
distribution (e.g., a company’s private data) often differs sig- 179

180 nificantly from the original distribution the model was trained  
 181 on (e.g., general web data). This domain shift can exacerbate  
 182 the overfitting problem, as the model struggles to generalize  
 183 from the source distribution to the target distribution.

184 To address this, we fine-tune the LLM on a mixture of data  
 185 sources, combining the company’s private data with publicly  
 186 available, related data (e.g., open-source documents). By ex-  
 187 posing the model to a more diverse set of data during fine-  
 188 tuning, we aim to reduce the discrepancy between the source  
 189 and target distributions, thereby improving the model’s abil-  
 190 ity to generalize.

191 Specifically, our fine-tuning approach involves training the  
 192 LLM on a balanced mixture of private company data and rel-  
 193 evant open-source data. The intuition is that the open-source  
 194 data, while not identical to the target domain, can help the  
 195 model learn more robust representations that are less sensitive  
 196 to the idiosyncrasies of the private data alone. By reducing  
 197 the domain shift between the fine-tuning data and the original  
 198 model training data, we expect to enhance the model’s per-  
 199 formance on a wide range of samples from the target domain.  
 200 We evaluate the effectiveness of our approach on text gen-  
 201 eration tasks, such as question-answering, and find that fine-  
 202 tuning on a mixture of private and open-source data indeed  
 203 helps reduce overfitting compared to fine-tuning on private  
 204 data alone. This is a promising result, as direct access to the  
 205 original data used to train the LLM is often unavailable, mak-  
 206 ing our approach a practical solution for domain-specific fine-  
 207 tuning.

### 208 3.1 Problem Statement

209 We consider a supervised learning task where the datasets are  
 210 defined as Cartesian products between features spaces  $\mathcal{X}$  and  
 211 label spaces  $\mathcal{Y}$ . We consider different datasets, each as a col-  
 212 lection of points generated by an underlying distribution, as  
 213 follows:

- 214 • Source distribution  $\mathcal{S}$  over  $\mathcal{X} \times \mathcal{Y}$ , where the collection  
 215 of points  $S = \{(x_i, y_i) \in (\mathcal{X} \times \mathcal{Y})\}_{i=1}^m$  are drawn in-  
 216 dependently and identical distributed (i.i.d.) from  $\mathcal{S}$ . It  
 217 indicates the set used to pre-train the foundation LLM.
- 218 • Domain-specific distribution  $\mathcal{D}$ , such that the points in  
 219 the dataset  $D = \{(x_i, y_i) \in (\mathcal{X} \times \mathcal{Y})\}_{i=1}^n$ , drawn i.i.d.  
 220 from  $\mathcal{D}$ , represent the proprietary data.
- 221 • Open-source distribution  $\mathcal{O}$ , assumed similar to  $\mathcal{S}$ , such  
 222 that the points in  $O = \{(x_i, y_i) \in (\mathcal{X} \times \mathcal{Y})\}_{i=1}^n$  are  
 223 drawn i.i.d. from  $\mathcal{O}$ .
- 224 • Target distribution  $\mathcal{T}$  over  $\mathcal{X} \times \mathcal{Y}$ , a mixture of  $\mathcal{D}$  and  
 225  $\mathcal{O}$ :

$$226 \quad \mathcal{T} = \alpha\mathcal{D} + (1 - \alpha)\mathcal{O}, \quad (1)$$

227 where  $\alpha \in [0, 1]$  is the mixing ratio. In this case, the  
 228 collection of points in  $T = \{(x_i, y_i) \in (\mathcal{X} \times \mathcal{Y})\}_{i=1}^n$ ,  
 are drawn from  $\mathcal{T}$ .

229 Let  $\mathcal{H}$  be an hypothesis space such that the hypothesis  $h \in \mathcal{H}$   
 230 is a function  $h : \mathcal{X} \rightarrow \mathcal{Y}$ . Consider  $h_S$  the hypothesis learnt  
 231 by minimizing the expected loss over  $\mathcal{S}$  (corresponding to  
 232 the LLM to fine tune in our case). The hypothesis  $h_S$  is the  
 233 solution of the empirical risk minimization (ERM) problem

over the source distribution, given by:

$$234 \quad h_S = \arg \min_{h \in \mathcal{H}} \mathbb{E}_{(x,y) \sim \mathcal{S}} [\ell(h(x), y)]. \quad (2)$$

The  $\ell$  term is a loss function which in our case is the cross-  
 entropy loss, defined as:

$$236 \quad \ell(h(x), y) = - \sum_{c=1}^C y_c \log h_c(x), \quad (3)$$

where  $y$  is one-hot encoded label vector,  $C$  is the number of  
 classes, and  $h_c(x)$  is the predicted probability of class  $c$  for  
 input  $x$ . In our case, the domain adaptation problem involves  
 adapting the  $h_S$  function to minimize the loss over the target  
 distribution  $\mathcal{T}$ . The learnt hypothesis  $h_{\mathcal{T}}$  is then the solution  
 of the following ERM problem:

$$242 \quad h_{\mathcal{T}} = \arg \min_{h \in \mathcal{H}|_{h_S}} \mathbb{E}_{(x,y) \sim \mathcal{T}} [\ell(h(x), y)], \quad (4)$$

where  $\mathcal{H}|_{h_S}$  means that the exploration of the hypothesis  
 space is initialized at the the point  $h_S$ .

Adapting the hypothesis  $h_S$  to the distribution  $\mathcal{T}$  involves  
 addressing the discrepancy between the distributions  $\mathcal{S}$  and  
 $\mathcal{D}$ . In fact, even though we are interested in applying the  
 learnt hypothesis  $h_{\mathcal{T}}$  on the points  $(\mathbf{x}, \mathbf{y}) \sim \mathcal{D}$ , fitting  $h_S$   
 directly to  $\mathcal{D}$  can lead to overfitting due to the divergence be-  
 tween  $\mathcal{S}$  and  $\mathcal{D}$ . By performing fine-tuning on the target dis-  
 tribution  $\mathcal{T}$ , which is a mixture of distributions  $\mathcal{O}$  and  $\mathcal{D}$ , we  
 aim to leverage the similarity between  $\mathcal{S}$  and  $\mathcal{O}$  to mitigate  
 the outlying nature of  $\mathcal{D}$  more effectively than  $\mathcal{D}$  alone would  
 do. Based on empirical observations, we find that:

$$244 \quad \text{JS-Divergence}(\mathcal{D}, \mathcal{O}) > \text{JS-Divergence}(\mathcal{D}, \mathcal{T}), \quad (5)$$

and under the assumption that  $\mathcal{S}$  and  $\mathcal{O}$  are similar, we claim  
 that:

$$246 \quad \text{JS-Divergence}(\mathcal{D}, \mathcal{S}) \geq \text{JS-Divergence}(\mathcal{D}, \mathcal{T}). \quad (6)$$

This inequality explains the effectiveness of fine tuning over a  
 mixture of distribution between the domain specific data and  
 opensource data which are assumed similar to the source one.  
 By reducing the overall divergence between the training dis-  
 tribution  $\mathcal{T}$  and the original source distribution  $\mathcal{S}$ , it facilitates  
 a smoother adaptation of the model  $h_S$ , enhancing its ability  
 to generalize from training to real-world data.

The divergence used is the *Jensen-Shannon* divergence (JS-  
 Divergence) [Lin, 1991], which is a popular measure of dis-  
 tance between two probability distributions. It is defined as  
 the average of the Kullback-Leibler divergences [Kullback  
 and Leibler, 1951] of each distribution to the mean of both  
 distributions, providing a symmetric and bounded measure.  
 Mathematically, it is given by:

$$257 \quad \text{JS-Divergence}(P, Q) = \frac{1}{2} \text{KL}(P \parallel M) + \frac{1}{2} \text{KL}(Q \parallel M), \quad (7)$$

where  $P$  and  $Q$  are the two distributions,  $M = \frac{1}{2}(P + Q)$  is  
 their mean, and KL denotes the Kullback-Leibler divergence.  
 This measure is particularly useful in scenarios where the dis-  
 tributions may not overlap completely, as it remains finite un-  
 der such conditions. The properties of being symmetric and  
 bounded between 0 and 1 make JS-Divergence a robust tool  
 for quantifying distributional discrepancies, especially in do-  
 main adaptation scenarios.

## 3.2 Generalization and Theoretical Bounds

The generalization performance of  $h_{\mathcal{T}}$  is influenced not only by the number of samples used during training but also by the divergence between the mixed training distribution  $\mathcal{T}$  and the target distribution  $\mathcal{D}$ . Building upon the foundational work by [Mansour *et al.*, 2009] we can provide a generalization error of a hypothesis bounded by the Rademacher Complexity ( $\mathcal{R}$ ) of a hypothesis space  $\mathcal{H}$  [Shalev-Shwartz and Ben-David, 2014; Mohri *et al.*, 2018], and the *Discrepancy* introduced in [Mansour *et al.*, 2009; Mohri and Muñoz Medina, 2012], which is a type of  $\mathcal{H}\Delta\mathcal{H}$  – *divergence* between two distributions. With probability at least  $1 - \delta$  we have:

$$\mathcal{L}_{\mathcal{D}}(\hat{h}_{\mathcal{T}}) - \mathcal{L}_{\mathcal{D}}(h_{\mathcal{D}}^*) \leq 4\mathcal{R}_{\mathcal{T},n}(\mathcal{H} |_{h_S}) + d_{\mathcal{H}|_{h_S}\Delta\mathcal{H}|_{h_S}}(\mathcal{T}, \mathcal{D}) + d_{\mathcal{H}\Delta\mathcal{H}}(\mathcal{T}, \mathcal{D}), \quad (8)$$

which becomes

$$\mathcal{L}_{\mathcal{D}}(\hat{h}_{\mathcal{T}}) - \mathcal{L}_{\mathcal{D}}(h_{\mathcal{D}}^*) \leq \mathcal{O}\left(\frac{\sqrt{d + \log 1/\delta}}{\sqrt{n}}\right) + d_{\mathcal{H}|_{h_S}\Delta\mathcal{H}|_{h_S}}(\mathcal{T}, \mathcal{D}) + d_{\mathcal{H}\Delta\mathcal{H}}(\mathcal{T}, \mathcal{D}), \quad (9)$$

where  $\mathcal{L}_{\mathcal{D}(h)} = \mathbb{E}_{(x,y)\sim\mathcal{D}}[\ell(h(x), y)]$ ,  $\hat{h}_{\mathcal{T}}$  is the empirical risk minimizer over the mixture distribution  $\mathcal{T}$ ,  $h_{\mathcal{D}}^*$  is the true minimizer over  $\mathcal{D}$ ,  $\mathcal{H} |_{h_S}$  represents the hypothesis space constrained by source domain knowledge,  $d_{\mathcal{H}\Delta\mathcal{H}}(\mathcal{T}, \mathcal{D})$  is the *Discrepancy* and  $n$  is the number of training points. This formulation supports our methodology by highlight how mixed-data fine-tuning serves as an effective domain adaptation strategy. By blending domain-specific and open-source data, we aim to craft a hypothesis that not only fits well to the training data but also exhibits robust generalization across diverse real-world applications. In practice, while the theoretical model uses  $\mathcal{H}\Delta\mathcal{H}$  – *divergence* for its rigorous properties, our empirical evaluation employs JS-Divergence due to its computational efficiency and its practical effectiveness in capturing the essential aspect of distributions shifts.

## 4 Experiments

### 4.1 Overview

In this study, we fine-tuned an open-source LLM, specifically the mistral-7b-Instruct-v02 [Jiang *et al.*, 2023], utilizing a combination of domain-specific data and open-source data. The fine-tuning process employed QLORA (Quantized Low-Rank Adaptation) [Dettmers *et al.*, 2024], which is designed to reduce the model complexity and size, thereby enabling efficient fine-tuning. We explored various mixtures of private company data and open-source data from public domain to construct our mixed training set to use during the fine-tuning phase. This approach allowed us to examine the impact of different data proportions on the model’s performance. The evaluation was consistently carried out on a held-out test set comprised exclusively of private company data, corresponding the domain specific data. We performed experiments focusing on a text-generation tasks, specifically for question-and-answer scenarios.

Moreover, to assess the distribution shift between the datasets, we computed the Jensen-Shannon divergence, providing a quantifiable measure of dataset similarity.

### 4.2 Dataset

The domain-specific dataset was derived from technical manuals and documentation related to the manufacturing, testing, and assembly of industrial assets within the energy sector. This dataset is highly specialized, containing information that has likely never been exposed to the public domain, thus representing a set of highly out-of-distribution samples with respect the source distribution the original LLM was trained on. Some examples of question and answering reported below:

- "Q": "What are the traditional monitored parameters for oil?"
- "A": "The traditional monitored parameters for oils are viscosity and oxidation."
- "Q": "Why should the traditional monitored parameters be used for turbine ?"
- "A": "These parameters are used to trend and predict the remaining useful life of the asset, helping to prevent operational problems from developing due to the condition of external environment."

The dataset comprises approximately 3,000 samples of specific question-and-answer texts, meticulously curated to reflect the unique context of the energy industry.

For the open-source dataset, we utilized the Alpaca dataset [Taori *et al.*, 2023], publicly available on Hugging Face and comprising 52,000 instructions and demonstrations generated by OpenAI’s text-davinci-003 engine. This dataset is commonly used for conducting instructional tuning on language model to enhance their ability to follow directions more precisely [Jiang *et al.*, 2023]. For the purposes of this experiments, we selected 3,000 samples from the Alpaca dataset to match the number of points used in the domain-specific dataset.

The two datasets were then blended in varying proportions, with subsequent testing conducted solely on the domain-specific dataset to isolate the effects of the mixed training data.

### 4.3 QLORA Technique

The QLORA technique is a variant of the Low-Rank Adaptation (LORA) methodology [Hu *et al.*, 2021] which involves modifying the parameterization of the neural network by introducing low-rank matrices that approximate the update to the weights during training. This method significantly reduces the number of trainable parameters, which minimizes memory usage and computational demands, making it suitable for fine-tuning large models on specialized datasets. By applying QLORA, we aim to maintain or even enhance the model’s performance while mitigating the risk of overfitting to the highly specialized domain data.

### 4.4 Experimental Setup

The experiments were conducted on high-performance computing environment equipped with DGX NVIDIA 8xA100

GPU, with with 40 GB of memory. This setup ensured efficient handling of the large models and extensive data involved. We implemented the experiments using Python, leveraging libraries such as Transformers [Wolf *et al.*, 2019] and PyTorch [Paszke *et al.*, 2019], which provide a robust frameworks for training and manipulating large-scale language models. For our experiments, QLORA was applied to all linear layers of the model to efficiently adapt the pre-trained weights with minimal computational overhead. We set the low-rank adaption factor  $\alpha$  equal to 8 and the rank  $r$  equal to 8 as well. We employed Adam optimizer [Kingma and Ba, 2014] and a cosine learning rate scheduler starting from an initial learning rate of  $2 \times 10^{-4}$ , which adapts the learning rate cyclically based on epoch count. A weight decay of 0.1 was applied to prevent overfitting, alongside a dropout rate of 0.05. Models were trained for up to 150 epochs, with early stopping employed to halt the training if the validation loss ceased to improve, ensuring efficient use of the computational resources. Each fine-tuning experiment varied the ratio of domain-specific to open-source data to identify the optimal conditions for model performance. We meticulously tracked the model’s behavior under each configuration to asses how variations in data mixture affect the learning outcomes. The performance metrics and detailed analysis of these experiments will be presented in the results section.

## 5 Results and Analysis

### 5.1 Jensen-Shannon Divergence Calculation

To evaluate the effectiveness of our mixed-data fine-tuning approach, we quantified the distribution shifts between different dataset configurations using the Jensen-Shannon divergence (JS-Divergence). This metric was instrumental in assessing how well the mixed dataset aligns with both the domain-specific and open-source datasets, providing a basis for understanding the impact of our data blending strategy on model generalization.

Dataset 1	Dataset 2	Discrepancy
Domain Specific	Open Source	0.62
Domain Specific	Mixed Dataset	0.37

Table 1: Jensen-Shannon divergence values quantifying discrepancies between different dataset configurations. Lower values indicate greater similarity between datasets.

The results, as summarized in Table 1, reveal significant insights into the dynamics of dataset integration. The divergence between the domain-specific and open-source dataset was notably high 0.62, indicating substantial differences in their distributions. By introducing a mixed dataset, the divergence from the domain-specific dataset decrease to 0.37. This reduction in divergence suggests that mixing the data has effectively made the distribution of the training data more representative.

These findings support the hypothesis that a well-blended training dataset can bridge the gap between diverse data sources, thus mitigating potential overfitting issues when the

model is applied exclusively to domain-specific data. The reduced Jensen-Shannon divergence value indicates that the mixed dataset shares more characteristics with both parent sets, potentially leading to improved generalization across varied data domains. Given the impact of dataset mixing on reducing discrepancy we aim to observe a mitigation of the overfitting effect.

### 5.2 Results of Fine-Tuning

We conducted several experiments where we modified the composition of the training set while keeping the held-out test set unchanged (solely composed of proprietary domain specific data). Initially, we focused on fine-tuning the model using the proprietary data of our company. Figure 2a illustrates that when the model is trained solely on domain-specific data, there is a significant deviation between the test loss and the training loss. This discrepancy indicates that the model is overfitting to the domain data. As a result, we proceeded with an additional experiment, fine-tuning the model exclusively on open-source data and evaluating its performance on the same domain-specific test set. The plots in Figure 2b once again reveal a divergence between the test and training losses, confirming the occurrence of overfitting in this case as well. These findings are consistent with the results obtained from the JS-Divergence analysis, which highlights the substantial dissimilarity between the open-source data and the domain-specific data.

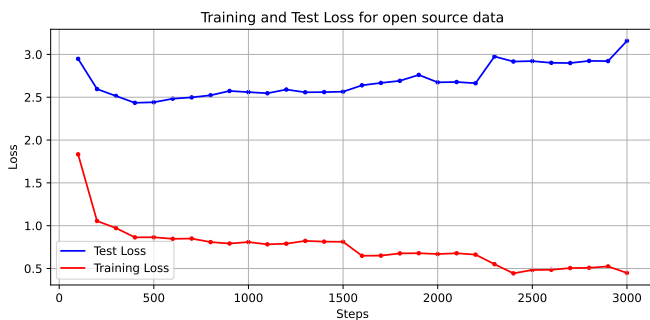

We then proceeded on performing fine-tuning of the model over a mixed dataset comprising both open-source and domain-specific data, varying the mixing weight  $\alpha$  as described in Equation 1. We tested different levels of mixture, ranging from  $\alpha = 1$  (using only domain-specific data) to  $\alpha \in [0.2, 0.5, 0.8]$  (mixing different proportions of domain and open-source data), and finally  $\alpha = 0.0$  (fine-tuning solely on open-source data). For each training run, we evaluated the model on the same held-out test set composed exclusively of domain-specific data, as our primary interest was to improve the model’s performance on the specific data domain.

Figure 3b illustrates the results obtained on the test set. Surprisingly, we observe that fine-tuning over a mixture dataset effectively mitigated the overfitting phenomenon. Indeed, all the test loss curves obtained by the models trained on the mixture dataset were lower than those obtained differently, and they tended to converge within the training loss, while the others diverged, as we can observe by comparing the test loss curves and the training ones in Figure 3a. Moreover, the best result was achieved using  $\alpha = 0.5$ , indicating that a balanced mix between open and private data led to a better mitigation effect.

We hypothesize that the regularization effect was achieved by reducing the distribution shift between the mixed data and the domain-specific data. This is supported by the observation that the Jensen-Shannon divergence between the open-source data and the domain-specific data is higher compared to the divergence between the mixed data and the domain-specific data. It is worth noting that there exists a positive correlation between reducing the divergence among the datasets and the mitigating effect observed. This implies that supervised fine-tuning on a mixed dataset serves as a regularization tech-

(a) Training loss curve during fine-tuning on domain-specific (private) data, and the corresponding test loss curve evaluated on a held-out domain-specific dataset.

(b) An overfitting case: training loss curve during fine-tuning on open-source data, and the test loss curve evaluated on a domain-specific dataset, demonstrating a divergence between the two losses.

Figure 2: Comparison of fine-tuning performance on domain-specific (private) data and open-source data. (a) Fine-tuning on domain-specific data only, showing the training loss curve on the domain-specific data and the corresponding test loss curve evaluated on a held-out domain-specific dataset. (b) Fine-tuning on open-source data only evaluated on a held-out domain-specific dataset, illustrating an overfitting case where the test loss on the domain-specific dataset diverges from the training loss on the open-source data. The results highlight the challenges of domain shift and the need for regularization techniques when fine-tuning on out-of-distribution data.

nique. Our empirical findings demonstrate that, particularly during fine-tuning on out-of-distribution data such as domain-specific data, the integration of datasets with reduced discrepancy values can help prevent the occurrence of overfitting.

### Effect of Increasing Dataset Size

To further investigate the benefits of fine-tuning on a mixed dataset, we conducted an additional experiment where we doubled the size of the training data while maintaining the optimal mixing ratio of  $\alpha = 0.5$  between open-source and domain-specific data. We then evaluated the fine-tuned model on the held-out domain-specific test set, and the results are depicted in Figure 4.

Interestingly, the model trained on the larger mixed dataset did not exhibit overfitting, and more importantly, it achieved better convergence compared to the previous experiments with a smaller dataset. This observation not only reinforces the notion that mixing datasets can effectively prevent overfitting, but it also suggests that increasing the number of training samples can lead to further performance improvements.

The training loss curve and the test loss curve in Figure 4 demonstrate a desirable trend: the test loss closely follows the training loss, indicating that the model generalizes well to the unseen domain-specific data. This behavior contrasts with the overfitting observed when training solely on the domain-specific dataset or on the open-source dataset alone, where the test loss diverged from the training loss.

Our findings suggest that the regularization effect introduced by mixing datasets can be amplified by increasing the overall size of the training data. The larger and more diverse the combined dataset, the more effective the regularization becomes, leading to better generalization and prevention of overfitting. This phenomenon aligns with the well-established principle in machine learning that larger and more diverse training datasets can help models capture broader patterns and improve their ability to generalize to unseen data distributions.

In summary, this experiment not only corroborates the effectiveness of mixing datasets in mitigating overfitting but also highlights the potential benefits of increasing the overall training data size when working with domain-specific or out-of-distribution data. By combining these two strategies, we can leverage the regularizing effect of data mixing while also benefiting from the increased diversity and information provided by larger datasets.

## 6 Conclusions

This study presents a novel approach to fine-tuning LLMs for industry-specific applications by leveraging a strategic combination of private company data and open-source data. Our findings demonstrate that this mixed-dataset fine-tuning methodology can effectively mitigate the risk of overfitting that often arises when training LLMs solely on narrow, domain-specific datasets. The key contributions of this work include empirical evidence that incorporating open-source data alongside private company data during the fine-tuning process leads to superior performance compared to using private data alone. This blended approach helps to reduce the distribution shift between the training and test data, acting

(a) The figure depicts the training losses of the model during the fine-tuning process using datasets that combine open-source and domain-specific data. The legend denotes the different mixing weights used:  $\alpha = 1$  corresponds to the utilization of exclusively domain-specific data,  $\alpha = 0$  represents the exclusive use of open-source data, and  $\alpha \in [0.2, 0.5, 0.8]$  indicates varying proportions of domain and open-source data.

(b) The figure illustrates the test losses of the model throughout the fine-tuning process, utilizing training datasets that combine open-source and domain-specific data. The alpha values represent the proportions of private and open-source data used for training, as explained in the caption of Figure 3a.

Figure 3: Comparison of training and test losses during fine-tuning on mixed datasets comprising open-source and domain-specific data and tested. (a) Training losses for models fine-tuned with varying mixing weights ( $\alpha$ ) between the two data sources. (b) Test losses evaluated on a held-out domain-specific dataset for the same fine-tuned models. The results demonstrate the effectiveness of fine-tuning on a mixed dataset in mitigating overfitting, with the optimal performance achieved at  $\alpha = 0.5$ , indicating a balanced mix between open-source and domain-specific data.

Figure 4: Fine-tuning performance on a larger mixed dataset with mixing ratio  $\alpha = 0.5$ . The training and test loss curves on the held-out domain-specific dataset exhibit desirable convergence, with the test loss closely following the training loss, contrasting the overfitting observed when fine-tuning on single datasets. The results suggest that increasing the overall training data size while maintaining an optimal mixing ratio can amplify the regularization effect of dataset mixing.

as a regularizer and enhancing the LLM’s ability to generalize, by mitigating the risk of overfitting. Additionally, our analysis of the Jensen-Shannon divergence between the private and open-source datasets reveals a correlation between reduced data divergence and improved model performance, underscoring the importance of carefully curating the dataset mixture to bridge the gap between diverse data sources and prevent overfitting. This work also provides a practical solution for industry-specific adaptation of LLMs, demonstrating how the strategic combination of private and open-source data can unlock the full potential of these models while addressing critical concerns around data privacy and model reliability in real-world applications. By addressing the challenges of data scarcity and domain shift in industry-specific settings, this study paves the way for more effective deployment of LLMs in sectors such as energy, where data confidentiality and model performance are of paramount importance. Overall, the principles and insights gleaned from this work can also inform the broader field of domain adaptation in machine learning, enriching our understanding of how to leverage diverse data sources to enhance model generalization.

## 6.1 Future works

In future research, our investigation will focus on assessing the effectiveness of the proposed fine-tuning methodology on other domain-specific datasets. Given the limited availability of additional data, it becomes imperative to expand the scope of analysis in order to evaluate the generalizability and robustness of the approach across various domains. It is important to emphasize the significance of supervised fine-tuning on domain-specific data, as it serves as a fundamental and crucial step for improved alignment techniques such as RLFH and DPO. By incorporating these advanced techniques, we can further enhance the performance and alignment of the model. Therefore, in our ongoing fine-tuning process, exploration DPO emerges as a valuable next step.
