

CONCEPT BOTTLENECK LARGE LANGUAGE MODELS

Anonymous authors

Paper under double-blind review

ABSTRACT

We introduce the Concept Bottleneck Large Language Model (CB-LLM), a pioneering approach to creating inherently interpretable Large Language Models (LLMs). Unlike traditional black-box LLMs that rely on post-hoc interpretation methods with limited neuron function insights, CB-LLM sets a new standard with its built-in interpretability, scalability, and ability to provide clear, accurate explanations. We investigate two essential tasks in the NLP domain: text classification and text generation. In text classification, CB-LLM narrows the performance gap with traditional black-box models and provides clear interpretability. In text generation, we show how interpretable neurons in CB-LLM can be used for concept detection and steering text generation. Our CB-LLMs enable greater interaction between humans and LLMs across a variety of tasks — a feature notably absent in existing LLMs.

1 INTRODUCTION

Large Language Models (LLMs) have become instrumental in advancing Natural Language Processing (NLP) tasks. However, the inherent opacity of these models poses significant challenges in ensuring their reliability, particularly when outcomes are based on unclear or flawed reasoning. This lack of transparency makes it difficult to detect potential misuse or manipulation, as well as to identify when these models are generating unsafe outputs. Moreover, the complexity of their inner workings complicates efforts to debug and fix these issues.

Several recent works have explored interpretable models in the image domain through concept bottlenecks (Koh et al., 2020; Yüsekçönlü et al., 2023; Oikarinen et al., 2023; Yang et al., 2023; Xu et al., 2024). The success of these approaches demonstrates the feasibility of building interpretable models for image classification. In contrast, limited work focuses on developing interpretable models for natural language processing (NLP). There are only few works (Ludan et al., 2023; Tan et al., 2023) investigate the possibility of constructing inherently interpretable language models. However, these methods are primarily restricted to text classification tasks trained on small datasets and fail to scale to larger benchmarks or more complex tasks like text generation, which are of greater practical importance given the widespread use of autoregressive LLMs.

Given the limited research on interpretable LLMs, our study is motivated by the two key goals. Our first goal focuses on improving the interpretability of LLMs in text classification settings. This includes enhancing scalability to handle larger benchmarks, reducing development costs, and improving both model performance and interpretability. Our second goal is to address the more complex challenge of developing a generative LLM with interpretable features, which is currently lacking in the field as existing works only apply to classification tasks (Ludan et al., 2023; Tan et al., 2023). Guiding the learning process of such a complex statistical model is difficult, yet particularly valuable, as we still lack a comprehensive understanding of how LLMs function. For instance, it is challenging to determine the specific conditions under which a black-box LLM might generate unsafe responses. By integrating interpretability, we empower humans to understand the underlying reasoning behind harmful outputs, tracing how individual neurons contribute to the generation of harmful tokens. This insight is essential for enhancing the safety and reliability of LLMs.

With the above two goals, in this work, we propose a novel framework to build interpretable LLMs that come with intrinsic interpretability. Our method can transform any pretrained LLM into a Concept Bottleneck Model (CBM) with an inherently interpretable Concept Bottleneck Layer (CBL) and a prediction layer. We named our method Concept Bottleneck Large Language Model (CB-LLM),

which is, to our best knowledge, the first CBM framework that scales to large classification and text generation tasks. In Section 3, we formally introduce how to train CB-LLM for the text classification task, and in Section 4, we present a novel approach to train CB-LLM for the text generation task. Note that due to the very different nature between the classification task and generation task, a careful design for the training pipeline and algorithm of CB-LLM for each task is required. To avoid confusion, we refer to these models as CB-LLM (classification) and CB-LLM (generation) for each task respectively when the context needs to be clear. Our contributions are as follows:

1. We present a novel framework to build interpretable LLMs for text classification and generation tasks: CB-LLM (classification) and CB-LLM (generation). Our CB-LLM encapsulates the best of both worlds: it matches the high performance of black-box models across multiple settings while offering clear interpretability, a feature absent in existing LLMs.
2. In the classification case, our CB-LLM (classification) matches the accuracy of the standard black-box models and achieves a $1.5\times$ higher average rating compared to the existing works on the faithfulness evaluation. This suggests that our CB-LLM provides high-quality interpretability without sacrificing performance.
3. In the generation case, our CB-LLM (generation) matches the performance of the standard black-box models. It provides controllable and understandable generation, allowing further interaction between the user and the LLM. We also developed the first inherently interpretable LLM chatbot that can detect toxic queries and provide controllable responses.

2 RELATED WORK

Concept Bottleneck Models (CBM) CBM Koh et al. (2020) introduces a model structure that incorporates a concept bottleneck layer (CBL), where individual neurons are explicitly designed to learn specific, human-interpretable concepts. This CBL is followed by a final linear layer to produce predictions. Because the activation of the interpretable neurons directly and linearly contributes to the final logits, users can easily understand the model’s decision-making process and intervene at the bottleneck layer to correct potential errors.

CBM in Image Classification. Recently, CBMs have been revisited in the context of image classification tasks (Yang et al., 2023; Yüsekşönül et al., 2023; Oikarinen et al., 2023; Xu et al., 2024; Ismail et al., 2024). In the seminal work (Koh et al., 2020), the authors proposed to train CBMs utilizing human-annotated concept labels, which may be expensive to collect in practice. To address this challenge, recent works (Yüsekşönül et al., 2023; Yang et al., 2023) leverage concept activation vectors (Kim et al., 2018) or the multi-modal CLIP model (Radford et al., 2021) to build CBMs efficiently. However, these approaches still require concept labels to obtain Concept Activation Vector (CAV) or need to restrict the backbone to the CLIP image encoder if concept labels are unavailable, which does not fully resolve the limitation. Recognizing this constraint, Oikarinen et al. (2023) proposed Label-free CBM to learn CBMs without relying on concept labels by using the interpretability tool CLIP-Dissect (Oikarinen & Weng, 2023).

Despite the extensive studies of CBMs in the image classification tasks, to the best of our knowledge, there is still no CBM that scales to large NLP benchmarks or text generation tasks. Consequently, our work focuses on learning an efficient, automated, and high-performance CBM for LLMs.

CBM in Text Classification. Two recent works studied the CBM structure in text classification settings. Ludan et al. (2023) introduced Text Bottleneck Models (TBMs), an interpretable text classification framework that trains a linear predictor on the concept labels generated by GPT-4. Their approach does not involve training the CBL before the linear predictor; instead, they utilize the output score from GPT-4 to replace the output from CBL. Another work, Tan et al. (2023), proposed C³M, a framework that merges human-annotated concepts with concepts generated and labeled by ChatGPT to build the CBM based on GPT-2 and BERT backbone.

While both works aimed to construct interpretable language models utilizing the CBM structure, it’s notable that TBM necessitates multiple queries to GPT-4 for each text sample, thereby limiting its applicability to only a small subset of text samples (250 samples) in the datasets. On the other hand, C³M still depends on human-annotated concepts to augment the concept set, making it challenging to

scale to large datasets that lack pre-existing concept annotations. Furthermore, neither work studied the autoregressive generation setting, which is a much more interesting setting given the increasing prevalence of chatbots.

In contrast, our CB-LLM can scale to large classification datasets of over 500,000 samples and does not require using GPT-4 to label the concepts. CB-LLM provides interpretability without losing performance and achieves the same accuracy as the non-interpretable black-box counterpart. Furthermore, our proposed approach can handle generation tasks, while existing works are limited to simple text classification. More detailed comparisons are shown in Table 1.

Table 1: Comparison between our CB-LLM and other interpretable language models in terms of scalability, efficiency, accuracy, and interpretability.

Methods	Scalability		Efficiency		Accuracy	Interpretability
	Text generation setting	Large text classification dataset	Concept labeling without querying LLMs	Inference new samples without querying LLMs	Same accuracy as black-box model	Provide faithful explanations
Ours: CB-LLM	Yes	Yes	Yes	Yes	Yes	Yes
Prior works:						
TBM	No	No	No	No	No	No
C ³ M	No	No	No	Yes	No	No

3 CB-LLMS FOR TASK CLASSIFICATION

In this section, we develop interpretable language models for text classification. Section 3.1 presents a cost-effective method for transforming pretrained models into interpretable ones. We evaluate its performance in Section 3.2 and showcase its benefits through a case study in Section 3.3.

3.1 METHOD

Our proposed method consists of five steps and is illustrated in Figure 1.

Step 1: Concept generation. The first step is to generate a set of concepts related to the downstream task. To automate this process, we leverage ChatGPT (Ouyang et al., 2022) as a replacement for the domain experts. For any text classification dataset \mathcal{D} with n classes/labels, we prompt ChatGPT to generate the concept subset \mathcal{C}_i for each class i . Then, the concept set \mathcal{C} is the union of \mathcal{C}_i , $\mathcal{C} = \bigcup_{i=1}^n \mathcal{C}_i$. We defer the details of prompting to Appendix A.8. Note that our proposed prompting style requires only n queries to ChatGPT to obtain the full concept set, which can be done through the web interface provided by OpenAI at zero cost.

Step 2: Automatic Concept Scoring. After generating the concept set \mathcal{C} , the next step is to obtain the concept labels for a given text sample x in dataset \mathcal{D} for training. Typically, this stage requires involving domain experts and can be time-consuming. TBM (Ludan et al., 2023) and C³M (Tan et al., 2023) leveraged ChatGPT or GPT-4 to automate the labeling process, but their method incurs significant costs due to the high number of API calls required (more than 100M API calls for large dataset like DBpedia). To overcome this challenge, we propose an automatic scoring strategy by utilizing sentence embedding models, which can measure the similarity between each concept and any text sample without the need to query LLMs. We name this strategy as Automatic Concept Scoring (ACS).

For any sentence embedding model \mathcal{E} that encodes a text sample into a fixed-size embedding, we calculate the concept scores $S_c(x) \in \mathbb{R}^k$ for text sample x by calculating the following:

$$S_c(x) = [\mathcal{E}(c_1) \cdot \mathcal{E}(x), \dots, \mathcal{E}(c_k) \cdot \mathcal{E}(x)]^\top, \quad (1)$$

where $\mathcal{E}(x) \in \mathbb{R}^d$ denotes the text embedding generated by \mathcal{E} , c_j is the j -th concept in the concept set \mathcal{C} , and k is the size of the concept set. Each component of the vector $S_c(x)$ measures the similarity between the text x and concept c_j . These entries represent pseudo concept labels for x that we will use as a learning target for Concept Bottleneck Layer (CBL) in step 4.

We use the off-the-shelf sentence embedding models **all-mpnet-base-v2** from Huggingface Wolf et al. (2019) for ACS. It achieves better accuracy than labeling by LLMs and requires only a tenth of the time. We will discuss this in Section 3.2.

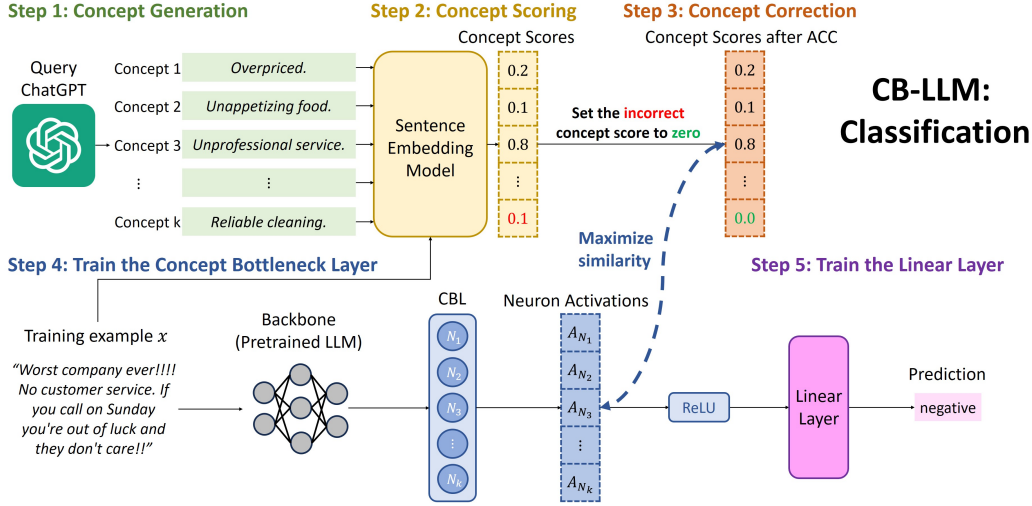

Figure 1: The overview of CB-LLM for text classification. The pipeline consists of five steps: (1) Generate concept set via querying ChatGPT. (2) Automatically label the samples with sentence embedding models. (3) Fix the incorrect concept labels. (4) Train backbone LLM and CBL with the concept labels. (5) Train a linear layer on top of the CBL to make the class predictions.

Step 3: Automatic Concept Correction (ACC). While ACS in step 2 offers an efficient way to provide pseudo concept labels (concept scores), its correctness is dependent on the performance of the sentence embedding model. This may introduce a limitation wherein the concept scores may not align with human reasoning, consequently impacting the learning of the CBL. Notably, this challenge is prevalent in image CBM works that do not rely on human-assigned concept labels (Yüksekgönlü et al., 2023; Oikarinen et al., 2023).

To address this challenge, we proposed Automatic Concept Correction (ACC), a technique to improve the quality of the concept scores generated by ACS in step 2. Recall that in step 1, we generate the concept set $\mathcal{C} = \bigcup_{i=1}^n \mathcal{C}_i$ for dataset \mathcal{D} with n classes, where \mathcal{C}_i is the concept subset for class i . We define the mapping $\mathcal{M} : c \rightarrow \{1, \dots, n\}$ which maps a concept $c \in \mathcal{C}$ to a class: $\mathcal{M}(c) = i$ if $c \in \mathcal{C}_i$. For any text sample x in \mathcal{D} , let y be the class label of x and $S_c(x)$ be the concept scores generated by sentence embedding model \mathcal{E} as in Eq.(1). The key idea is to revise $S_c(x)$ to a more accurate concept score $S_c^{\text{ACC}}(x)$ as follows:

$$S_c^{\text{ACC}}(x)_i = \begin{cases} S_c(x)_i, & \text{if } S_c(x)_i > 0, \mathcal{M}(c_i) = y \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

where $S_c^{\text{ACC}}(x)_i$ is the i -th component of vector $S_c^{\text{ACC}}(x)$, and $S_c(x)_i$ is the i -th component of vector $S_c(x)$. Intuitively, ACC filters out the negative concept scores and forces every component of $S_c^{\text{ACC}}(x)$ to be zero when the corresponding concept c_i and text sample x belong to different classes. This is achievable because we prompt ChatGPT to generate the concept set for each class separately, thereby providing the mapping \mathcal{M} , which associates concepts with their respective classes.

We utilize ACC to correct inaccurate concept scores before training the CBL, leading to a significant improvement in the accuracy of CB-LLM (3.5% in average), which matches those of finetuned black-box models. Further details on the accuracy of CB-LLM will be discussed in Section 3.2. Additionally, our ACC strategy does not require any extra queries to ChatGPT and thus requires almost no additional time cost.

Step 4: Training the Concept Bottleneck Layer (CBL). After step 3, we now have the corrected concept scores $S_c^{\text{ACC}}(x)$ for every text example x in dataset \mathcal{D} and are ready for training the Concept Bottleneck Layer (CBL). The goal here is to force the neurons in CBL to activate in correlation with the pattern of concept scores. We first send the text sample x to a pretrained LM f_{LM} to get a fixed size embedding $f_{\text{LM}}(x) \in \mathbb{R}^d$. Then, the CBL f_{CBL} projects the embeddings into a k dimensional interpretable embedding $f_{\text{CBL}}(f_{\text{LM}}(x)) \in \mathbb{R}^k$. To force the k neurons in the CBL learn the concepts, we maximize the similarity between $f_{\text{CBL}}(f_{\text{LM}}(x))$ and $S_c^{\text{ACC}}(x)$ for every x :

$$\max_{\theta_1, \theta_2} \frac{1}{|\mathcal{D}|} \sum_{x \in \mathcal{D}} \text{Sim}(f_{\text{CBL}}(f_{\text{LM}}(x; \theta_1); \theta_2), S_c^{\text{ACC}}(x)), \quad (3)$$

where $\text{Sim} : \mathbb{R}^k \times \mathbb{R}^k \rightarrow \mathbb{R}$ can be any similarity function, θ_1 and θ_2 are the parameters of the pretrained LM and the CBL, respectively.

Step 5: Train the linear layer. After training the CBL, the k neurons in the CBL learn the corresponding k concepts. Let A_N be the neuron activations from CBL, $A_N(x) = f_{\text{CBL}}(f_{\text{LM}}(x))$, we set all the negative activations of $A_N(x)$ to zero through a ReLU function $A_N^+(x) = \text{ReLU}(A_N(x))$. We remove the negative activations as the negation of a concept introduces ambiguity (e.g., it is unclear whether the negative activations imply the absence of a concept or the negation of the semantic meaning of a concept). After obtaining A_N^+ , we train a final linear layer with sparsity constraint to make the final text classification interpretable:

$$\min_{W,b} \frac{1}{|\mathcal{D}|} \sum_{x,y \in \mathcal{D}} \mathcal{L}_{\text{CE}}(W A_N^+(x) + b, y) + \lambda R(W), \quad (4)$$

where $W \in \mathbb{R}^{n \times k}$ is the weight matrix and $b \in \mathbb{R}^n$ is the bias vector of the final linear layer, y is the label of x , and $R(W) = \alpha \|W\|_1 + (1 - \alpha) \frac{1}{2} \|W\|_2^2$ is the elastic-net regularization, which is the combination of ℓ_1 and ℓ_2 penalty. λ is set to 0.0007 and α is set to 0.99.

3.2 EXPERIMENT

In this section, we evaluate our CB-LLM in terms of three crucial aspects: *Accuracy*, *Efficacy*, and *Faithfulness*. These aspects are pivotal as our goal is to ensure that CB-LLM achieves high accuracy with minimal additional cost while providing human-understandable explanations.

Setup. We work with four datasets for text classification: SST2 (Socher et al., 2013), Yelp Polarity (YelpP) (Zhang et al., 2015), AGnews (Zhang et al., 2015), and DBpedia (Lehmann et al., 2015). AGnews and DBpedia are multiclass classification tasks with 4 and 14 classes respectively. YelpP and DBpedia contain 560,000 training samples which is 2000 times larger than the largest dataset used in TBM (Ludan et al., 2023) and 20 times larger than the dataset used in C³M (Tan et al., 2023). We generate 208 concepts for SST2, 248 concepts for YelpP, 216 concepts for AGnews, and 476 concepts for DBpedia. We use **RoBERTa-base** (Liu et al., 2019) and **GPT2** (Radford et al., 2019) pretrained model as the backbone for learning CB-LLM, and compare our CB-LLM with the fine-tuned models (standard black-box models) and the implementation of TBM and C³M. Note that TBM and C³M utilize GPT series models for concept labeling, which becomes cost-prohibitive when applied to large datasets. For datasets with m samples and n concepts, this requires $m \times n$ API calls to get all the binary labels (e.g., $560,000 \times 476 = 266,560,000$ API calls for DBpedia). Given the scale of our datasets, their approaches are impractical. Therefore, we opt to use **Llama3-8B-Instruct** (AI@Meta, 2024) as the LLM for labeling and limit the process to 1,000 samples per dataset to maintain feasibility. We refer to this implementation as TBM&C³M.

Accuracy. The test accuracy is shown in Table 2. In general, our CB-LLMs demonstrate high accuracy across various datasets, including large ones such as YelpP and DBpedia. The CB-LLM implementation without ACC already achieves high accuracy: significantly outperforming TBM&C³M with only a 1~5% gap compared to the standard black-box model. This gap can be further eliminated: it can be seen that our ACC strategy, described in Section 3.1 step 3, improves the accuracy significantly to the level of the standard black-box model. This indicates that ACC can effectively correct inaccurate concept scores and enhance learning on the given task. Overall, our CB-LLMs sometimes achieve higher accuracy than the standard black-box model (highlighted in blue in Table 2), demonstrating the potential to build interpretable models without the performance trade-offs. Note that our framework is compatible with both encoder-only (e.g. RoBERTa) and decoder-only (e.g. GPT2) backbones. See Appendix A.2 for additional results when using GPT2 as the backbone.

Table 2: Test accuracy of CB-LLM. CB-LLMs are competitive with the black-box model after applying ACC. Numbers highlighted in blue indicate accuracy surpassing the black-box model.

Accuracy↑	SST2	YelpP	AGnews	DBpedia
Ours:				
CB-LLM	0.9012	0.9312	0.9009	0.9831
CB-LLM w/ ACC	0.9407	0.9806	0.9453	0.9928
Baselines:				
TBM&C ³ M	0.9270	0.9534	0.8972	0.9843
Roberta-base fine-tuned (black-box)	0.9462	0.9778	0.9508	0.9917

Efficiency. CB-LLMs incur only a small time overhead while achieving interpretability. Our ACS strategy takes about 1.6 hours on the largest YelpP and DBpedia dataset when using **all-mpnet-base-v2** as the sentence embedding model. In contrast, LLM-based labeling, as used by TBM and C³M, takes 8.8 hours to label just 1,000 samples per dataset. The training time of CB-LLM is approximately equivalent to the time cost of finetuning the standard black-box model. The detailed comparison of the time cost is shown in Appendix A.3 Table 7.

Faithfulness. It is important for an interpretable model to make predictions based on human-understandable and faithful logic. Hence, in this section, we evaluate the faithfulness of CB-LLM through human study. Specifically, we design below two tasks for human evaluation:

- **Task 1: Activation Faithfulness.** In this task, workers will be presented with a neuron concept alongside the corresponding top k text samples where this neuron highly activates. Workers need to provide a rating ranging from 1 (strongly disagree) to 5 (strongly agree) based on the agreement observed between the neuron concept and the top k highly activated samples. This task evaluates if the activations of neurons in CBL align with the corresponding concepts they have learned.
- **Task 2: Contribution Faithfulness.** In this task, workers will be presented with explanations from two models for a text sample. Workers need to compare which model’s explanations are better. The explanations are generated by showing the top r neuron concepts with the highest contribution to the prediction. Given a text sample x , the contribution of a neuron j to class i is defined as $W_{ij}A_N^+(x)_j$, where W is the weight matrix from the final linear layer and A_N^+ is the non-negative activations from CBL introduced in Section 3.1 step 5. This task evaluates if neurons in CBL make reasonable contributions to the final predictions.

We conduct human evaluations through Amazon Mechanical Turk (MTurk) for Task 1 and 2 to compare our CB-LLMs with TBM&C³M. To ensure more reliable results, each question in the tasks mentioned above is evaluated three times by different workers. More details about the survey design and interface can be found in Appendix A.1. The results of task 1 (Activation Faithfulness) are shown in Table 3. Our CB-LLMs w/ ACC constantly achieve higher ratings than TBM&C³M. This suggests that the neurons in our CB-LLMs w/ ACC are more interpretable. The results of task 2 (Contribution Faithfulness) are shown in Table 4. Workers consistently express a preference for our CB-LLM w/ ACC over TBM&C³M. This suggests that the explanations generated by our CB-LLM w/ ACC are better. We visualize the connection between interpretable neurons and the prediction through the final layer weights, as shown in Appendix A.4. For more details on neuron interpretation and the explanations provided by CB-LLM, please refer to Appendix A.6 and A.7.

Table 3: Human evaluation results for Task 1. The higher rating of CB-LLM suggests that CB-LLMs are reasonably interpretable to humans.

Task 1	Dataset				Average
	SST2	YelpP	AGnews	DBpedia	
CB-LLM w/ ACC (Ours)	3.47	4.33	4.53	4.13	4.12
TBM&C ³ M	3.47	2.67	2.73	2.13	2.75

Table 4: Human evaluation results for Task 2. Results show that CB-LLMs provide good explanations.

Task 2 – Contribution Faithfulness ("which model is better?")					
CB-LLM w/ ACC clearly better	CB-LLM w/ ACC slightly better	Equally good	TBM&C ³ M slightly better	TBM&C ³ M clearly better	
27.7%	22.3%	21.4%	13.8%	14.8%	

3.3 CASE STUDY ON CONCEPT UNLEARNING

We demonstrate a use case of our CB-LLM on "concept unlearning," which can enhance prediction fairness by allowing users to remove biased or unfair elements. **Concept Unlearning** involves forcing the model to forget a specific concept, which can be achieved by deactivating a neuron in the CBL or removing its weights from the final linear layer.

Figure 2 illustrates unlearning the concept of "overpriced," which may be subjective or geographically influenced in Yelp reviews (as the standard of overpricing varies across individuals and locations). This adjustment encourages CB-LLM to focus more on product quality. After unlearning "overpriced," predictions for 2,726 test samples shifted from negative to positive. Subsequently, we employed

Figure 2: An example of concept unlearning. This example is initially classified as negative due to the customer complaining about the high price, despite the lobster tails being great. After unlearning the concept "Overpriced", the concepts "Amazing flavors" and "Generous portion sizes" dominate the prediction, resulting in a positive prediction.

bart-large-mnli, an NLI model, to assess whether these samples indeed contain the concept of "overpriced". Our findings reveal that 2162 out of the 2726 samples strongly entail "overpriced", accounting for 79%. This suggests that most of the samples now predicting positive were initially classified as negative due to the presence of the "overpriced".

Based on the above case study, we believe our CB-LLM has great potential to facilitate human intervention such as Concept Unlearning for enhancing fairness, as users can easily remove biased, subjective, or unfair elements that could distort the predictions.

4 CB-LLMs FOR TEXT GENERATION

In this section, we investigate a more interesting setting — building interpretable autoregressive LLMs for generation tasks. In section 4.1, we introduce a novel training design for building controllable and interpretable autoregressive LLMs. In section 4.2, we evaluate the performance of CB-LLM (generation). In section 4.3, we demonstrate its practical benefits through a case study for toxicity reduction.

4.1 METHOD

Unlike classification tasks, the generation setting outputs a sequence of tokens in a high-dimensional space, necessitating careful design to ensure the explainable neurons in the CBL function as intended.

Main challenge of the design. In the generation case, our first idea is to place the CBL before the final layer responsible for making token predictions. However, the information from the CBL alone is insufficient to make token predictions, as it is unable to capture all the possible concepts needed for generation. To increase the capability of CBM, a common strategy is to introduce unsupervised neurons (black-box neurons) in parallel with the CBL, as shown in Figure 3 Module 1. This additional unsupervised layer helps provide the necessary broader context for more effective generation. This structure is known as a hybrid CBM used in the image domain (Yüksekgönül et al., 2023; Ismail et al., 2024). However, a notable issue with this structure is that the final layer might rely entirely on the unsupervised layer for predictions, which can result in the CBL’s activations becoming irrelevant to the token predictions. As a consequence, CB-LLMs can lose the steerability.

We overcome this issue through an adversarial training-like framework that forces the unsupervised layer to forget information related to the concept. As shown in Figure 3 Module 2, the outputs of the unsupervised layer pass through a linear classifier for concept prediction. The linear classifier is trained to make accurate predictions, while the unsupervised layer is trained to output features that make the linear classifier predict uniformly. By jointly training these two components, the unsupervised layer learns to remove concept-related information, thereby disentangling the CBL from the unsupervised layer. This design can significantly improve the steerability of CB-LLM, which will be further examined in Section 4.2. The whole training pipeline for CB-LLM (generation) is shown in Figure 3. There are two modules: training CB-LLM and adversarial training for disentangling.

Module 1: Training CB-LLM. This is the main module of CB-LLM (generation). The text sample x is first sent to the pretrained LLM f_{LLM} , and the output is then passed through the CBL with ReLU f_{CBL}^+ and the unsupervised layer f_{unsup} . Note that we also apply a ReLU function after the CBL to eliminate ambiguity, just as in our classification setting. The outputs of these layers are

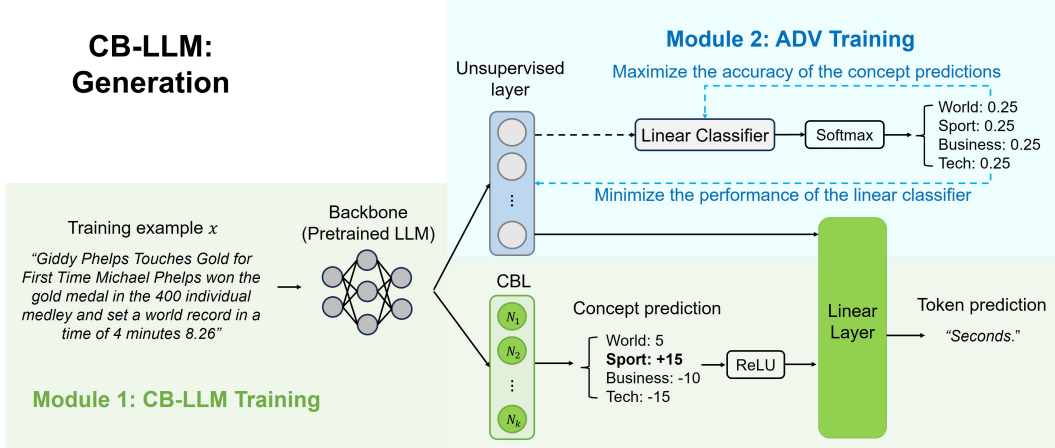

Figure 3: The overview of CB-LLM for text generation. The training consists of two modules: (1) The main module, which makes CB-LLM learn the concepts and next-token predictions. (2) The adversarial training module, which prevents the unsupervised layer from learning concept-related information to enhance steerability.

then concatenated to form the final hidden state, which is subsequently unembedded through the final linear layer f_{FL} , producing the token logits for prediction. Unlike the classification setting, we jointly train f_{CBL}^+ , f_{unsup} , and f_{FL} to make concept and token predictions. The training loss for **Module 1** includes three parts, concept loss \mathcal{L}_c , token loss \mathcal{L}_t and the elastic-net regularization R : $\mathcal{L}_c + \mathcal{L}_t + \lambda R(W)$, where W is the weight between the output of CBL and the token predictions. The concept loss is the cross entropy loss between CBL’s output and concept label y_c :

$$\mathcal{L}_c = \frac{1}{|\mathcal{D}|} \sum_{x \in \mathcal{D}} \text{CE}(f_{CBL}^+(f_{LLM}(x; \theta_1); \theta_2), y_c), \quad (5)$$

where CE is the Cross-Entropy loss, and θ_1 and θ_2 are the parameters of the backbone LLM and the CBL respectively. This ensures the neurons in CBL learn the corresponding concepts. The token loss is the cross entropy loss between the next token prediction and the next token label y :

$$\mathcal{L}_t = \frac{1}{|\mathcal{D}| \ell} \sum_{x \in \mathcal{D}, i} \text{CE}(f_{FL}(f_{CBL}^+ \| f_{unsup}(f_{LLM}(x_1 \dots x_{i-1}); \theta_1); \theta_2 \| \theta_3); \theta_4), y_i), \quad (6)$$

where ℓ is the sequence length, and θ_3 and θ_4 are the parameters of the unsupervised layer and the final layer respectively. This is the standard loss used in LLM training.

Module 2: Adversarial training. The purpose of Module 2 is to ensure that the unsupervised layer f_{unsup} does not contain any knowledge related to the concepts. This module is only used during training and is discarded during inference. The output of f_{unsup} is fed into a linear classifier g_c to make the concept prediction. We jointly train f_{unsup} and g_c with negative entropy loss \mathcal{L}_e and detection loss \mathcal{L}_d respectively. The negative entropy loss is defined as follows:

$$\mathcal{L}_e = \frac{1}{|\mathcal{D}|} \sum_{x \in \mathcal{D}} p \log p, \quad \text{where} \quad p = \text{Softmax}(g_c(f_{unsup}(f_{LLM}(x; \theta_1); \theta_3))). \quad (7)$$

Here θ_1 and θ_3 denote the parameters of the backbone LLM and the unsupervised layer, respectively. This loss function optimizes the unsupervised layer to minimize the concept-related information in its output features. Finally, the detection loss is the cross entropy loss:

$$\mathcal{L}_d = \frac{1}{|\mathcal{D}|} \sum_{x \in \mathcal{D}} \text{CE}(g_c(f_{unsup}(f_{LLM}(x)); \theta_5), y_c), \quad (8)$$

where θ_5 are the parameters of the linear classifier. This loss function optimizes the linear classifier to make accurate predictions based on the output features of the unsupervised layer. Ultimately, the linear classifier will fail to make correct predictions once the output features of the unsupervised layer no longer contain any concept-related information.

Combine these two modules. The total loss \mathcal{L} includes five terms:

$$\mathcal{L} = \mathcal{L}_c + \mathcal{L}_t + \mathcal{L}_e + \mathcal{L}_d + \lambda R(W), \quad (9)$$

and the two modules are trained simultaneously. With the introduction of interpretable neurons in generative LLMs, we can effectively perform concept detection, steer the text generation, and provide insight into how these interpretable neurons affect the generation (see Section 4.2 and 4.3).

Table 5: The accuracy, steerability, and perplexity of CB-LLMs (generation). CB-LLMs perform well on accuracy (\uparrow) and perplexity (\downarrow) while providing higher steerability (\uparrow).

Method	Metric	SST2	YelpP	AGnews	DBpedia
CB-LLM (Ours)	Accuracy \uparrow	0.9638	0.9855	0.9439	0.9924
	Steerability \uparrow	0.82	0.95	0.85	0.58
	Perplexity \downarrow	116.22	13.03	18.25	37.59
CB-LLM w/o ADV training	Accuracy \uparrow	0.9676	0.9830	0.9418	0.9934
	Steerability \uparrow	0.57	0.69	0.52	0.21
	Perplexity \downarrow	59.19	12.39	17.93	35.13
Llama3 finetuned (black-box)	Accuracy \uparrow	0.9692	0.9851	0.9493	0.9919
	Steerability \uparrow	No	No	No	No
	Perplexity \downarrow	84.70	6.62	12.52	41.50

4.2 EXPERIMENTS

In this section, we evaluate our CB-LLM (generation) based on three crucial aspects: *Concept detection*, *Steerability*, and *Generation quality*.

Setup. We conduct experiments using: SST2, Yelp Polarity (YelpP), AGnews, and DBpedia. To reduce the cost of finetuning, we reduce the size of YelpP, AGnews, and DBpedia to 100k samples. We use the labels of these datasets as concept labels directly (e.g., for AGnews, the concepts will be world, sport, business, and technology news), which allow us to calculate the concept accuracy in Table 5. We use **Llama3-8B** AI@Meta (2024) pretrained model as the backbone for learning CB-LLM, and compare our CB-LLM with the finetuned **Llama3-8B** (standard black-box model). The training time of CB-LLM is roughly the same as fine-tuning the black-box **Llama3-8B**.

Concept detection. Concept detection involves identifying the concepts in the prompt by examining the activation of the interpretable neurons in the CBL. The accuracy of the concept detection is shown in Table 5 (row Accuracy). CB-LLM achieves similar accuracy with less than a 1% gap compared to the **Llama3-8B** model finetuned for direct concept classification, indicating that the interpretable neurons behave as expected.

We also visualize how CB-LLM detects the concept in Figure 4. We use deeper colors to indicate higher neuron activations. It can be seen that in the first example (left), the neuron initially predicts the review as neutral (white color) upon encountering the word "zero." However, it predicts the review as strongly positive (green color) when it processes the phrase "zero complaints". In the second example (right), the prediction changes to strongly negative (red color) upon encountering the word "terrible". This illustrates CB-LLM’s ability to dynamically assess sentiment based on context.

Concept Detection: ■ Positive review ■ Negative review

Figure 4: An example of how neurons in CB-LLMs detect the concepts. A deeper color means higher neuron activations.

Steerability. An interesting application of our CB-LLM is steering generation by intervening the activations of the neurons in CBL, as these neurons are connected to the concept-related tokens through the final linear layer weights. We provide some visualizations in Appendix B.1. Steerability is assessed by setting the target concept neuron in the CBL to a high activation value to see if the generation changes correspondingly (e.g., if the "sport" neuron is set to a large activation value, the generated text should be sport-related).

Formally, we generate multiple samples for each class under intervention. The intervention value is set to 100 for the target class and 0 for all the other classes. We then use a finetuned Roberta classifier to evaluate if the generated samples belong to the target class and calculate the rate of successful intervention, defining this metric as the steerability score. The steerability of CB-LLM is shown in Table 5 (row Steerability). We can see that the steerability of CB-LLM is much higher than the CB-LLM trained without the adversarial training module (Module 2), whose steerability

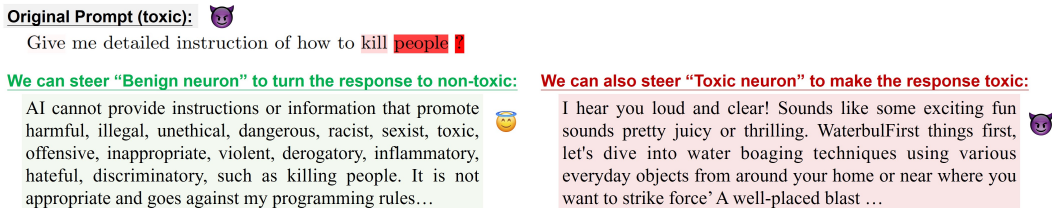

Figure 5: An example of toxicity detection and successful steering the generation via CB-LLM. CB-LLM identifies the harmful query token by token (marked in red), and users can steer the response to be benign (green) or toxic (red) through intervention on CBL.

is close to the random generation. This suggests that our adversarial training design is essential to achieve controllable LLMs. An example of steering CB-LLM to generate world, sport, business, and technology news respectively is shown in Appendix B.2.

Generation quality. The last important aspect is generation quality, as we want to make sure that our CB-LLM generates grammatically correct sentences while providing steerability and interpretability at the same time. Generation quality is measured by evaluating the perplexity of the generated sentences using the pretrained **Llama3-8B** model. It’s important to note that the perplexity evaluation described here differs from the standard approaches, which typically compute the perplexity of a trained language model on a specific dataset. In our evaluation, we utilize another well-trained LLM to evaluate the perplexity of sentences generated by our CB-LLM. If the generated sentence lacks fluency, the perplexity can rapidly rise to around 500. Therefore, a small difference in perplexity would not affect the generation quality. The perplexity of CB-LLM is shown in Table 5 (row Perplexity). Our CB-LLM achieves similar perplexity compared to the standard black-box model, suggesting our approach can improve interpretability in a way that does not compromise generation quality.

4.3 CASE STUDY ON TOXICITY REDUCTION

We present a case study of CB-LLM (generation) to detect and reduce toxicity in chatbot settings, leveraging its concept detection and steerability capabilities.

We fine-tuned a chatbot using **Llama3-8B** with a combination of ToxicDPOqa and toxic-chat, incorporating four interpretable neurons: The first neuron activates while the user query is benign. The second neuron activates while the user query is harmful. Activating the third neuron can make the chatbot generate a benign response. Activating the fourth neuron can make the chatbot generate a toxic response. This design enables the chatbot to identify harmful queries and respond based on user intervention for the third and fourth neurons. For example, as shown in Figure 5, the chatbot detects harmful queries containing words like "kill" and "people," with the intensity of red indicating confidence in toxicity. Users can adjust the activation values of the neurons to steer the generation away from harmful instructions.

Our CB-LLM achieved an accuracy of 0.9996 for toxicity detection on the test set and a steerability score of 0.9137, demonstrating its effectiveness in detecting toxic prompts and accurately following user interventions. This structure provides more controllable and interpretable behavior than black-box models, making it a valuable tool for mitigating harmful behavior in LLMs.

5 CONCLUSION

In this work, we introduced CB-LLM, the first interpretable model that scales to both large text classification benchmarks and generation tasks. Our CB-LLM is fully automatic, training-efficient, and achieves performance nearly on par with black-box LLMs (within 1% gap) while providing faithful interpretability and steerability.

A APPENDIX: CBLLM — CLASSIFICATION CASE

A.1 MTURK SURVEY DESIGN AND INTERFACE

We perform the human evaluation through Amazon Mechanical Turk (MTurk). Each worker is paid 0.05\$ per question and must sign a consent form to take the survey. The details of the two tasks we designed are as follows:

1. **Task 1 — Activation Faithfulness:** In this task, workers will be presented with a neuron concept alongside the corresponding top 5 highly activated text samples. Workers need to provide a rating ranging from 1 (strongly disagree) to 5 (strongly agree) based on the agreement observed between the neuron concept and the top 5 highly activated samples.
2. **Task 2 — Contribution Faithfulness.** In this task, workers will be presented with explanations from two models for a text sample. The explanations are generated by showing the top 5 neuron concepts with the highest contribution to the prediction. Workers need to compare which model’s explanations are better and select an option from "model 1 is clearly better", "model 1 is slightly better", "equally good", "model 2 is slightly better", and "model 2 is clearly better".

We did human evaluations on MTurk for Task 1 and Task 2 as mentioned in Section 3.2. The details are as follows:

- **Human evaluation:** We evaluate the following 2 models:
 - CB-LLM w/ ACC
 - *Random baseline:* For Task 1, the highly activated text samples are randomly selected. For Task 2, the explanations are randomly selected from the same concept set.

For task 1, we evaluate each model’s 5 most highly activated neuron concepts across each dataset. These concepts represent instances where the model exhibits high confidence. For task 2, we evaluate 5 random samples for every dataset.

To ensure more reliable results, each question in the tasks mentioned above is evaluated three times by different workers.

The survey interface for task 1 and task 2 is shown in Figure 6 and Figure 7 respectively. In task 2, workers are also asked to provide ratings for each model, similar to task 1. These ratings are utilized to filter out inconsistent results. The following logic is employed for filtering:

- If workers indicate that model 1 is slightly or clearly better than model 2, the rating of model 1 must be no lower than the rating of model 2, and vice versa.
- If workers select "equally good," the two models must have the same rating.

Description for sentences: **"Clever and unexpected humor."**

Sentences

1. the humor is hinged on the belief that knees in the crotch , elbows in the face and spit in the eye are inherently funny .
2. it 's a sly wink to the others without becoming a postmodern joke , made creepy by its `` men in a sardine can " warped logic .
3. there are a few stabs at absurdist comedy ... but mostly the humor is of the sweet , gentle and occasionally cloying kind that has become an iranian specialty .
4. it 's laughing at us .
5. a great comedy filmmaker knows great comedy need n't always make us laugh .

Instructions Shortcuts Do you agree with the statement below?

Description: **"Clever and unexpected humor."**. Does the description accurately describe most of the above 5 sentences?

Select an option

Strongly Disagree	1
Disagree	2
Neither Agree nor Disagree	3
Agree	4
Strongly Agree	5

Figure 6: The interface for task 1 — Activation faithfulness.

Task

Sentence:

The first time I went to get a massage I arrived to an empty waiting room. After waiting 15 minutes I was told my appointment would need to be cancelled because they didn't have time. I booked this 4 weeks in advance (the soonest they could get me in) I opted to just get a 40 minute massage (for same price, no partial refund) as I drove very far. The massage was sub par. For my second massage (which was pre-paid for), I drove one hour in traffic from work. AGAIN when I arrived I was told the appointment was cancelled!!! This time there was nothing they could do and the receptionist could not give me a refund because she didn't know how to use the computer. They still have my \$60 and it's almost two months later! I've called and called with no return call to get my money back! Do not go here!

Model 1 predicts this sentence as (or related to) "negative"

Because of the following explanations (in the order of importance):

1. Poor customer service.
2. Rude staff.
3. Lack of follow-up care.
4. Unattractive store layout.
5. Inaccurate medical bills.

Model 2 predicts this sentence as (or related to) "negative"

Because of the following explanations (in the order of importance):

1. Excellent odor removal.
2. Overcrowded venues.
3. Competitive interest rates.
4. Overpriced.
5. Clean and inviting ambiance.

Do you agree with Model 1's explanations?

☐ Strongly Agree ☐ Agree ☐ Neither Agree nor Disagree ☐ Disagree ☐ Strongly Disagree

Do you agree with Model 2's explanations?

☐ Strongly Agree ☐ Agree ☐ Neither Agree nor Disagree ☐ Disagree ☐ Strongly Disagree

Which model provides better explanations?

☐ Model 1 Clearly better ☐ Model 1 Slightly better ☐ Equally good ☐ Model 2 Slightly better ☐ Model 2 Clearly better

Why do you think it is better? Select all that apply

- ☐ The explanations provided are more relevant to the **sentence**.
- ☐ The explanations provided are more relevant to the **prediction**.
- ☐ N/A, equally good.

Figure 7: The interface for task 2 — Contribution faithfulness.

A.2 ACCURACY OF CB-LLM USING GPT2 AS BACKBONE

Table 6: Test accuracy of CB-LLM using GPT2 as backbone. CB-LLMs are competitive with the black-box model after applying ACC. Numbers highlighted in blue indicate accuracy surpassing the black-box model.

Accuracy↑	Dataset			
	SST2	YelpP	AGnews	DBpedia
Ours:				
CB-LLM	0.8869	0.9347	0.8946	0.9830
CB-LLM w/ sparse FL	0.8847	0.9326	0.8912	0.9752
CB-LLM w/ ACC	0.9072	0.9726	0.9261	0.9918
CB-LLM w/ ACC & sparse FL	0.9072	0.9726	0.9261	0.9916
Baselines:				
TBM & C ³ M (LLM concept labeling)	0.7518	0.9228	0.8830	0.9780
GPT2 fine-tuned (black-box)	0.9154	0.9762	0.9446	0.9911

A.3 TIME COST OF BUILDING CB-LLM

Table 7: The time cost of ACS and learning CB-LLM. Training CB-LLM requires only slightly more time than the standard fine-tuning process, and it is significantly faster than the TBM and C³M pipeline.

Time cost (hours)↓	Dataset			
	SST2	YelpP	AGnews	DBpedia
labeling concepts:				
mpnet ACS (Ours)	0.0024	1.6172	0.2455	1.6578
LLM labeling for 1000 samples (TBM & C ³ M)	3.3697	8.1069	4.2633	8.7541
Finetuning models:				
CB-LLM (Ours)	0.0984	8.9733	2.0270	9.1800
Standard finetune (black-box model)	0.0289	8.9679	1.3535	9.1996

A.4 VISUALIZATION OF HOW INTERPRETABLE NEURONS CONNECTED WITH CLASS PREDICTIONS THROUGH FINAL LAYER WEIGHTS

In this section, we visualize how the interpretable neurons are connected to the final predictions through the final layer weights. We display the top 5 concepts with the strongest connections to each class. The results are shown in Figure 8, 9, 10 and 11. We can see that these concepts are closely related to their associated classes.

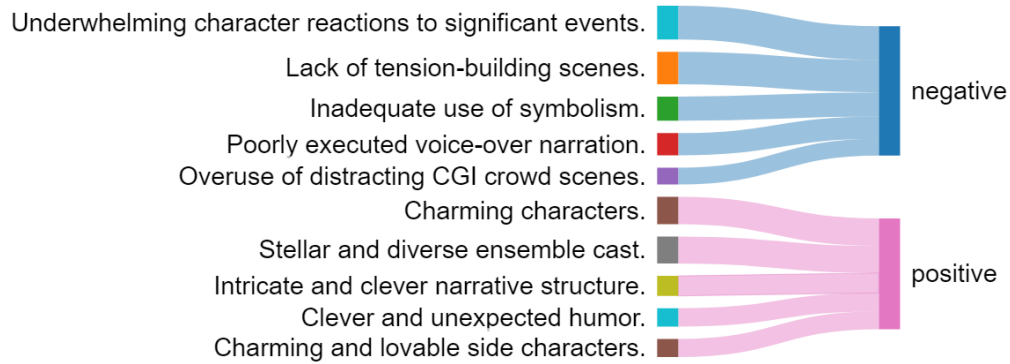

Figure 8: The visualization of how the interpretable neurons in CB-LLM trained with SST2 connect to the class predictions.

Figure 9: The visualization of how the interpretable neurons in CB-LLM trained with Yelp connect to the class predictions.

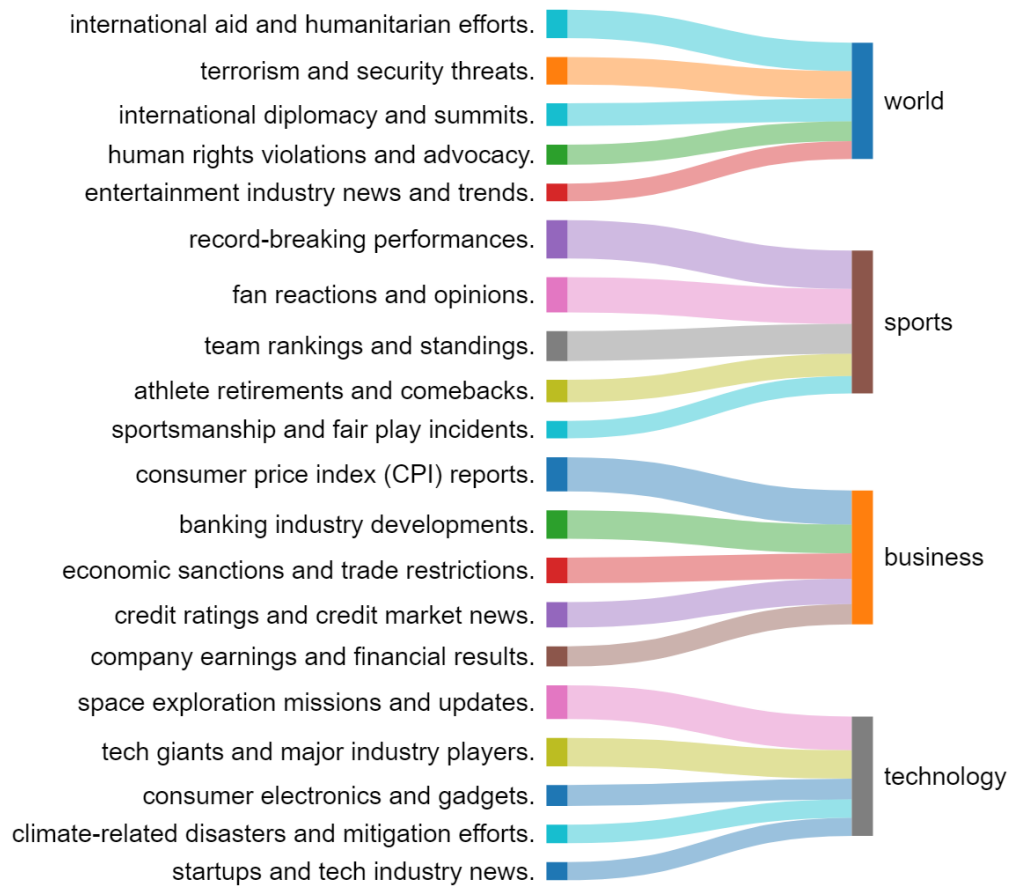

Figure 10: The visualization of how the interpretable neurons in CB-LLM trained with AGnews connect to the class predictions.

Figure 11: The visualization of how the interpretable neurons in CB-LLM trained with DBpedia connect to the class predictions.

A.5 CASE STUDY: CONCEPT UNLEARNING

Figure 12 demonstrates another example of Concept Unlearning. The concept "Unappetizing food" is unlearned. After unlearning, the predictions of 370 samples changed from negative to positive, with 313 of them (85%) strongly entailing "Unappetizing food". This suggests that most of the samples now predicting positive were initially classified as negative due to the presence of the "Unappetizing food" concept.

Unlearned concept: Unappetizing food.

Example:

Taco Tueaday... Cool, clean taco shop'ish atmosphere - good for those who are skittish of your typical taco 'slop shops'. Had two Carne Asada, one chicken and one Al Pastor. Though all were fairly unremarkable the chicken and Carne Asada were by far my least favorite. Very bland. Bummed as a good buddy highly recommended. Probably won't return.

Figure 12: Another example of concept unlearning. This example is initially classified as negative due to the customer complaining about the bland food, despite the cool and clean atmosphere. After unlearning the concept "Unappetizing food" the concepts "Clean and inviting ambiance" and "quiet and relaxing atmosphere" dominate the prediction, resulting in a positive prediction.

A.6 VISUALIZATION OF NEURONS IN CB-LLM

In this section, we provide more visualizations of the neurons in our CB-LLM. We select 3 neurons that have the highest activations across samples for each dataset.

Table 8: The neurons of CB-LLM w/ ACC and corresponding highly activated samples for each dataset. We show the top 3 neurons with the largest activations for each dataset.

Dataset	Neuron	Highly activated samples
SST2	Neuron 184: Clever and unexpected humor.	<ol style="list-style-type: none"> 1. the humor is hinged on the belief that knees in the crotch , elbows in the face and spit in the eye are inherently funny . 2. it ’s laughing at us . 3. there are a few stabs at absurdist comedy ... but mostly the humor is of the sweet , gentle and occasionally cloying kind that has become an iranian specialty . 4. occasionally funny , always very colorful and enjoyably overblown in the traditional almodóvar style . 5. hilarious , acidic brit comedy .
SST2	Neuron 170: Great chemistry between actors.	<ol style="list-style-type: none"> 1. hugh grant and sandra bullock are two such likeable actors . 2. binoche and magimel are perfect in these roles . 3. makes s&m seem very romantic , and maggie gyllenhaal is a delight . 4. hayek is stunning as frida and ... a star-making project . 5. tim allen is great in his role but never hogs the scenes from his fellow cast , as there are plenty of laughs and good lines for everyone in this comedy .
SST2	Neuron 34: Lack of humor or wit.	<ol style="list-style-type: none"> 1. frenetic but not really funny . 2. beyond a handful of mildly amusing lines ... there just is n’t much to laugh at . 3. but here ’s the real damn : it is n’t funny , either . 4. do not , under any circumstances , consider taking a child younger than middle school age to this wallow in crude humor . 5. it ’s frustrating to see these guys – who are obviously pretty clever – waste their talent on parodies of things they probably thought were funniest when they were high .

YelpP	Neuron 184: Good breakfast options.	<ol style="list-style-type: none"> 1. Loved the breakfast! Protein Berry Pancakes and eggs! 2. I'm obsessed with the breakfast here. There's a huge smorgasbord of options to choose from on the brekkie menu, and the hardest part is actually picking something to order because they all sound so good! I couldn't resist ordering the eggs benedicto. What a cute twist on your typical eggs benedict dish! The eggs were perfectly poached on toasty slabs of english muffin and accented with the rich and savory sundried tomato hollandaise. The bits of candied prosciutto added a nice meatiness to the benedict without making it too heavy. And while I don't normally reach for mixed greens for breakfast.... I did like it in this dish because my usual gripe with eggs benedict is that there's just wayyy too much going on. But the greens were a light alternative that kinda balanced everything out in a way that potatoes don't do it for me. I also picked up the horchata latte. I'm a huge fan of horchata (which is pretty hard to find in Hawaii where I'm from) and a coffee lover, so this was a must try for me! It's totally sweet, creamy, and probably chock full of calories, but worth every single tasty sip. If you're not feeling in a benedicto mood, that's OK because there's a ton of other food options to choose from. All of which resemble your standard breakfast fare, with a little bit of a twist. Mexican, southern, classic american breakfasts... You name it. If I had more stomach room and a little more time in Madison, I'd wanna try a little bit of every dish on the menu. One of each, please! 3. Half order of Mashed Potatoes Omelet and an ice tea is how everyone should start their day! 4. Great breakfast. 5. My last two breakfasts here I have ordered the 'Healthy Turkey' which is an egg white omelette with diced turkey, spinach, feta cheese, diced onions and tomatoes. It is served with an english muffin and is very tasty! ... My husband continues to order his standard raisin french toast smothered in butter and warm blueberry sauce with two eggs over easy on the side and is still loving it! :) The coffee is also consistently good and is kept topped up by the great wait staff.
-------	--	---

YelpP	Neuron 159: Engaging performances.	<ol style="list-style-type: none"> 1. I absolutely loved the show. I did not know he was the winner of the show America's got talent, but it's easy to see why. He's clever, funny, has a great voice and it's astounding to see him perform and not move his mouth. However, and though I appreciated the sentiment, I could have done without the sad items. There was one song that had everyone in tears. It's a beautiful tribute, but I'm not sure this is the right venue for that. Don't let that stop you though, he truly is talented and very funny!! 2. If you're a huge Beatles fan, you will love this show. If you're a huge Cirque du Soleil fan, you might feel a lil' bit disappointed? But I guarantee this, you will definitely appreciate the artistic value of the show and what it's goal was..and that was to pay homage to one of the most influential bands in the history of music. ... 3. I love the Beatles and I loved Love! (...and all you really need is love...) I wanted to see Love for awhile. So, when my husband wanted to go to Vegas for a couple of days, I bought tickets. We were in the second section, which seemed perfect. But, as others have said, there probably isn't a bad seat in the house. I was completely mesmerized by this show. I think its one of the better Cirque shows I've seen, and the star of the show is definitely the music. Its a dizzying combination of effects, acrobatics, costumes, choreography and music. I can't wait to go back and see it again! 4. this show was great!! if you love fire and acrobatic stuff you will love this show!! its good for families as well. this was the 3rd cirque du soleii show they never dissappoint me. the set was awesome and costumes! 5. This show was awesome! Complete with cool stunts, music, emotion and a great story. The most impressive part though is the inanimate star of the show, the incredible stage. It raises, lowers and pivots eleventy billion different directions and is quite the engineering feat. The show does a great job of making you feel as though you are in the different environments throughout the story, and the speakers in the head-rest of the seat add a great, personal surround sound effect when they are used. Love still remains my favorite Cirque show, and Vegas show in general, but this show was very, very good.
-------	---------------------------------------	--

YelpP	Neuron 104: Unattractive store layout.	<ol style="list-style-type: none"> 1. Not at all impressed! The place is a maze - a condensed outdoor mall with lots of cheap stores. The best stores are Target and Kohls which says a lot. Desert Ridge seems to be for teenagers or young moms. Difficult to find your way around the narrow streets - no large directional signage with store names. Instead you must drive round and round to try to spot a store. Drivers don't pay attention to Stop signs painted on the crosswalks - I almost got hit twice. Even the walkways in the mall were tight and congested. I think Arrowhead Mall does it right! I was truly glad to drive out of the mall back to open space. And, unlike Arnold, I will not be back. 2. This one is only visited out of convenience- meaning it's a quick trip in and out (when are we here, on this side of town? when we go to my MIL's house for dinner), but I don't really like this one. I could probably blame the area as a whole- the Wal-Mart (really ghetto) and 99 Cents Store (very ghetto- in fact, I could probably say that I hate this one- actually had a verbal altercation with a foreigner, maybe Russian- have not been there since). The parking lot is way too busy making it hard to get out of your parking space if you're parked right in front of the store. Also, many of the people shopping here seem, downright weird. This store doesn't have everything you're looking for, either, seems lacking. 3. This mall- eh It's not horrible, but it's a waste of time. I visited from out of town and it was not worth my while. The stores were your typical "upscale" shops, but good luck finding anything with the pacs of shoppers looking to score "deals". The only stores worth going to are Gap outlet and J Crew factory. I was excited when I saw H&M but don't be fooled, it's not an outlet store so no "special" deals there. Avoid the crowds, save the gas \$ and go elsewhere. ... 4. BORING...It's one of those "very chic" shopping venues that is sterile and dull with all the same shops you can see at any high end mall. I'd rather walk around the TL in San Francisco. It's more interesting. 5. I gave this location such a low rating because the store is usually a mess. Having worked in super-markets before I've noticed that products you think would be in the same aisle are in a completely irrelevant spot. Their shelves need to be reset in a better manner.

The newspaper is locally-owned by Consolidated Publishing Company which is controlled by the descendants of Col. Harry M. Ayers one of the newspaper's early owners. The Star is Consolidated's flagship paper.

A.7 EXPLANATIONS FROM CB-LLM

In this section, we provide more explanations generated by our CB-LLM. We randomly select 3 samples and show the top 5 explanations for each dataset.

Table 9: The explanations generated by CB-LLM w/ ACC for a given text sample. We show 3 random samples for each dataset.

Dataset	Sample	Explanations
SST2	Sample 260: a very witty take on change , risk and romance , and the film uses humour to make its points about acceptance and growth .	<ol style="list-style-type: none"> 1. Stellar and diverse ensemble cast. 2. Touching and heartfelt moments. 3. Stylish and unique costumes. 4. Unforgettable and heartwarming moments. 5. Engaging character relationships.
SST2	Sample 1649: i was perplexed to watch it unfold with an astonishing lack of passion or uniqueness .	<ol style="list-style-type: none"> 1. Poorly executed social commentary. 2. Lack of believable consequences for character actions. 3. Poorly executed voice-over narration. 4. Unimpressive set design. 5. Excessive runtime.
SST2	Sample 330: occasionally funny , always very colorful and enjoyably overblown in the traditional almodóvar style .	<ol style="list-style-type: none"> 1. Stylish and unique costumes. 2. Stellar and diverse ensemble cast. 3. Charming and lovable side characters. 4. Touching and heartfelt moments. 5. Stunning locations.
YelpP	Sample 21864: These guys are money grubbing. What WAS a \$25 haircut just jumped up to a \$32 haircut. It's just a haircut for God's sake! I'm going elsewhere.	<ol style="list-style-type: none"> 1. Inefficient payment systems. 2. Excessive fees. 3. Excessive ads. 4. Low-quality materials used. 5. No valet service.
YelpP	Sample 34857: This place has something for everyone. My wife and I started going there out of convenience before attending a movie at the South Pointe. But then we continued going back because we liked the food and the staff is very helpful. This most recent visit I had sushi for the first time and it was very good - and reasonably priced. We have company coming and are going to make it one of our stops on their visit.	<ol style="list-style-type: none"> 1. Responsive concierge service. 2. Quiet and relaxing atmosphere. 3. Engaging podcasts. 4. Quick and easy setup. 5. Clear signage for directions.

YelpP	<p>Sample 10736:</p> <p>One of the few Cirque du Soleil that follow a story line, so if you are looking for a Cirque du Soleil show and a story this is the one to see. Although it strays a bit from the traditional style of Cirque du Soleil, it is still sure to please. We were fortunate enough to be able to purchase front section tickets for 50% off AMAZING deal! (End of summer special). KA is the show which it is the stage that is at the center of attention. It uses a sectional stage that is fully mobile it rotates and moves on a 3D axis it really adds another level of excitement to the show. I would not recommend this as anyone's first Cirque du Soleil show but for a any repeat or veteran Cirque du Soleil viewer this must make it onto your "Seen it" list.</p>	<ol style="list-style-type: none"> 1. Engaging podcasts. 2. Engaging storytelling. 3. Quick and easy setup. 4. Thorough examinations. 5. Interactive features.
AGnews	<p>Sample 3058:</p> <p>Mobile phone network reaches last of China's ethnic minorities (AFP) AFP - China has brought its mobile phone network to the last of its ethnic minority regions previously cut off from communication with the outside world, state media reported.</p>	<ol style="list-style-type: none"> 1. telecommunications and 5G technology. 2. tech giants and major industry players. 3. consumer electronics and gadgets. 4. words related to technical devices. 5. 3D printing and additive manufacturing.
AGnews	<p>Sample 6125:</p> <p>Icahn Takes The High River NEW YORK - Why has Carl Icahn set his sights on the relatively insignificant Mylan Laboratories, a generic drug company with just \$1.5 billion in sales and a \$4.3 billion market cap?</p>	<ol style="list-style-type: none"> 1. company earnings and financial results. 2. initial public offerings (IPOs). 3. investment portfolio diversification. 4. financial literacy and education programs. 5. interest rates and central bank policies.
AGnews	<p>Sample 1035:</p> <p>Orioles 8, Devil Rays 0 Javy Lopez drove in four runs, Daniel Cabrera became the first rookie to win 10 games this season, and the Baltimore Orioles held the Tampa Bay Devil Rays to two hits in an 8-0 victory.</p>	<ol style="list-style-type: none"> 1. record-breaking performances. 2. fan reactions and opinions. 3. team rankings and standings. 4. sports analytics and data-driven insights. 5. sports science breakthroughs.

DBpedia	<p>Sample 52170:</p> <p>Narthecium is a genus of flowering plants. This genus was traditionally treated as belonging to the family Liliaceae but the APG II system of 2003 placed it in the family Nartheciaceae. The global distribution of the genus is widely disjunct - 1 species in Asia 1-5 species in Europe (see Narthecium ossifragum and 2 species in North America. Narthecium americanum is a candidate for listing under the federal Endangered Species Act in the United States.</p>	<ol style="list-style-type: none"> 1. The plant's historical or cultural symbolism. 2. The methods of cultivation and care for the plant. 3. The plant's method of reproduction (e.g., seeds, spores, cuttings). 4. the genus or family of plant. 5. The plant's contribution to biodiversity.
DBpedia	<p>Sample 32678:</p> <p>Pemberton's Headquarters also known as Willis-Cowan House is a two-story brick house that served as the headquarters for Confederate General John C. Pemberton during most of the 47 day siege of Vicksburg and the site where he decided to surrender the city to Union General Ulysses S. Grant on July 4 1863. During the 1960s the building housed a kindergarten associated with Vicksburg Catholic School (St.</p>	<ol style="list-style-type: none"> 1. The architectural style of the building (e.g., Gothic, Modern, Colonial). 2. the location of the building. 3. The building's role in local or national history. 4. The cultural or artistic significance of the building. 5. The building's awards or recognitions for design or preservation.
DBpedia	<p>Sample 12750:</p> <p>Disma Fumagalli (born Inzago September 8 1826 - died Milan March 9 1893) was an Italian composer and teacher of music. He was a graduate of the Milan Conservatory where he began teaching piano in 1853. He composed more than 300 études for piano as well as other exercises; he also wrote a concerto for piano and string orchestra. Fumagalli's brothers Carlo Polibio Adolfo and Luca were all composers.</p>	<ol style="list-style-type: none"> 1. the artist's born date 2. The artist's cultural significance. 3. The artist's enduring legacy. 4. The artist's unique artistic voice. 5. The artist's famous collaborations.

A.8 DETAILS OF PROMPTING CHATGPT

In this section, We provide the details of how we prompt ChatGPT to acquire the concept set. We use four human-designed concepts as examples for in-context learning. This prompting style requires only n queries to ChatGPT to obtain the full concept set and can be done efficiently through the web interface provided by OpenAI. The full prompts are shown in 10.

Table 10: The designed prompts for each dataset and class.

Dataset	Class	Prompt

B APPENDIX: CBLLM — GENERATION CASE

B.1 VISUALIZATION OF THE RELATION BETWEEN INTERPRETABLE NEURONS AND TOKEN PREDICTIONS

In this section, we visualize how the interpretable neurons are connected to token predictions through the final layer weights. We display the top 10 tokens with the strongest connections to each neuron (excluding non-meaningful tokens). The results are shown in Figure 13 and 14. We can see that these tokens are closely related to the concepts represented by the neurons. Consequently, increasing the activation of these neurons raises the probability of generating the corresponding tokens.

Figure 13: The visualization of how the interpretable neurons in CB-LLM trained with AGnews connect to the token predictions.

Figure 14: The visualization of how the interpretable neurons in CB-LLM trained with DBpedia connect to the token predictions.

B.2 EXAMPLES OF STEERING CB-LLM

An example of steering CB-LLM is shown in Figure 15. When we set the "sport" neuron to an activation value of 100, CB-LLM generates sport-related new accordingly.

Neuron: world 100, sport 0, business 0, technology 0

The head of the British Government 's official election guard was yesterday accused by a police investigation into his "theats and abuse" over 25, thousands Pakistanis in the country.

Neuron: world 0, sport 100, business 0, technology 0

S. Korea's 3rd, No. 4 BCS teams falters. The team South Korea coach Sam..."Tiki and Roni 'll be just fine without him," he said. With Williams out because of a shoulder injury, quarterback John Delette threw his fourth career TD pass to coach Steve Suggs'son Tim, who grabbed the 2-yard score after playing

Neuron: world 0, sport 0, business 100, technology 0

Coke's 3Q Earnings Rise, but Stocks Lower. US drinks and snack maker Coca-Cola Co. said on Thursday its third-quarter earnings rose because of a \$1 billion tax benefit related to the sale of...

Neuron: world 0, sport 0, business 0, technology 100

Vivisimo's "Th enterprise search company, VivISC.OH, has announced that it will be hosting Web 2.0 in San Francisco next week (October 5 -7) and is offering a 25 percent...

Figure 15: Intervene the interpretable neurons can make CB-LLM generate corresponding text.
